| Table S2. Details of the tested volatile organic compounds (VOCs). Also shown are their proton affinity (PA) values. | 5 |
| Table S3. Proton-transfer reaction rate constants (k_{ptr} , $\times 10^{-9} \text{ cm}^3 \text{ molec}^{-1} \text{ s}^{-1}$) from literature. | 6 |
| Table S4. The RH dependence, sensitivity, intercept of protonated adducts, and fragmented ions. | 7 |

Figures.

| | |
|--|----|
| Figure S1. The diagram of the RH experimental setup. MFC: mass flow controller. | 8 |
| Figure S2. The mass spectra of aromatic hydrocarbons (benzene, toluene, m-xylene, and 1,2,4-trimethylbenzene), and terpenoids (isoprene, α -pinene, and β -caryophyllene) in Vocus at a mixing ratio of ~ 12 ppbv (β -caryophyllene 1.2 ppbv). | 9 |
| Figure S3. The mass spectra of small aldehydes (formaldehyde and acetaldehyde), long-chain aldehydes (n-butanal, pentanal, and hexaldehyde), and ketones (acetone, and methyl ethyl ketone) in Vocus at a mixing ratio of ~ 12 ppbv. | 10 |
| Figure S4. The mass spectra of unsaturated aldehydes (acrolein and methacrolein), aromatic aldehydes (benzaldehyde and m-tolualdehyde), nitriles (acetonitrile and acrylonitrile), and methanol in Vocus at a mixing ratio of ~ 12 ppbv. | 11 |
| Figure S5. Time series of the protonated ion (MH^+) signals for selected (A) VOCs and (B) OVOCs as concentration varied from 0 to ~ 22 ppbv (~ 2 ppbv for β caryophyllene) under dry ($\text{MH} \sim 5\%$) conditions. Note the signals were magnified by 10 times for β -caryophyllene and 3 times for n-butanal, pentanal, and hexaldehyde. | 12 |
| Figure S6. Time series of the protonated ion (MH^+), adduct ions ($[\text{MH} + \text{H}_2\text{O}]^+$), and fragmented ions ($[\text{MH} - \text{H}_2\text{O}]^+$ and/or $[\text{MH} - \text{C}_x\text{H}_y]^+$) signals for n-butanal, pentanal, and hexaldehyde. Note that the time in x axis is not continuous, with some periods with noisy signals cut off. | 13 |
| Figure S7. The signal intensities (panels a, b, and c, and panels g, h, and i) and fractions (panels d, e, and f, and panels j, k, and l) of protonated ion (MH^+), adduct ions ($[\text{MH} + \text{H}_2\text{O}]^+$), and fragmented ions ($[\text{MH} - \text{H}_2\text{O}]^+$ and $[\text{MH} - \text{C}_x\text{H}_y]^+$) for α -pinene as functions of E/N ratio (a, d, g, and j), RF amplitude (b, e, h, and k), and BSQ amplitude (c, f, i, and l). The difference between a/d and g/j is that the former fixed N ($p = 2.0$ mbar) and varied axial voltage (V) to change E/N ratio, while the latter fixed V ($= 466$ volts) and varied p (i.e., N) to change E/N ratio. The difference between b/e and h/k and between c/f and i/l is that the former was at $p = 2.0$ mbar while the latter $p = 3.5$ mbar. If not varied, RF amplitude was set at 500 volts and BSQ amplitude at 300 volts. | 14 |
| Figure S8. The signal intensities (panels a, b, and c, and panels g, h, and i) and fractions (panels d, e, and f, and panels j, k, and l) of protonated ion (MH^+), adduct ions ($[\text{MH} + \text{H}_2\text{O}]^+$), and fragmented ions ($[\text{MH} - \text{H}_2\text{O}]^+$ and $[\text{MH} - \text{C}_x\text{H}_y]^+$) for 1,2,4-trimethylbenzene as functions of E/N ratio (a, d, g, and j), RF amplitude (b, e, h, and k), and BSQ amplitude (c, f, i, and l). The difference between a/d and g/j is that the former fixed N ($p = 2.0$ mbar) and varied axial voltage (V) to change E/N ratio, while the latter fixed V ($= 466$ volts) and varied p (i.e., N) to change E/N ratio. The difference between b/e and h/k and between c/f and i/l is that the former was at $p = 2.0$ mbar while the latter $p = 3.5$ mbar. If not varied, RF amplitude was set at 500 volts and BSQ amplitude at 300 volts. | 15 |
| Figure S9. The signal intensities (panels a, b, and c, and panels g, h, and i) and fractions (panels d, e, and f, and panels j, k, and l) of protonated ion (MH^+), adduct ions ($[\text{MH} + \text{H}_2\text{O}]^+$), and fragmented ions ($[\text{MH} - \text{H}_2\text{O}]^+$ and $[\text{MH} - \text{C}_x\text{H}_y]^+$) for acetone as functions of E/N ratio (a, d, g, and j), RF amplitude (b, e, h, and k), and BSQ amplitude (c, f, i, and l). The difference between a/d and g/j is that the former fixed N ($p = 2.0$ mbar) and varied axial voltage (V) to change E/N ratio, while the latter fixed V ($= 466$ volts) and varied p (i.e., N) to change E/N ratio. The difference between b/e and h/k and between c/f and i/l is that the former was at $p = 2.0$ mbar while the latter $p = 3.5$ mbar. If not varied, RF amplitude | |

| | | |
|-----|--|----|
| 72 | was set at 500 volts and BSQ amplitude at 300 volts. | 16 |
| 73 | Figure S10. The signal intensities (panels a, b, and c, and panels g, h, and i) and fractions | |
| 74 | (panels d, e, and f, and panels j, k, and l) of protonated ion (MH^+), adduct ions ($[MH +$ | |
| 75 | $H_2O]^+$), and fragmented ions ($[MH - H_2O]^+$ and $[MH - C_xH_y]^+$) for hexaldehyde as | |
| 76 | functions of E/N ratio (a, d, g, and j), RF amplitude (b, e, h, and k), and BSQ amplitude | |
| 77 | (c, f, i, and l). The difference between a/d and g/j is that the former fixed N ($p = 2.0$ mbar) | |
| 78 | and varied axial voltage (V) to change E/N ratio, while the latter fixed V ($= 466$ volts) and | |
| 79 | varied p (i.e., N) to change E/N ratio. The difference between b/e and h/k and between c/f | |
| 80 | and i/l is that the former was at $p = 2.0$ mbar while the latter $p = 3.5$ mbar. If not varied, | |
| 81 | RF amplitude was set at 500 volts and BSQ amplitude at 300 volts. | 17 |
| 82 | Figure S11. The ratio of α -pinene signals (MH^+ : 137 Th; $[MH - C_xH_y]^+$: 81 Th) to all ion | |
| 83 | signals. This was used to estimate the E/N ratio. | 18 |
| 84 | Figure S12. The sensitivity of acetone. An intercept above zero indicates a high background | |
| 85 | value. | 18 |
| 86 | Figure S13. The signal intensities of H_3O^+ , $H_3OH_2O^+$, and $H_3O(H_2O)_2^+$ as conditions varied as | |
| 87 | in Figures 3 in the main text and S14 below. | 19 |
| 88 | Figure S14. The ratio of the logarithm of intensity (panels a, b, and c) and the difference of | |
| 89 | fractional signal of the protonated ion (MH^+) among all ions (panels d, e, and f), when | |
| 90 | changing axial voltage (V) or FIMR pressure (p) (panels a and d), RF amplitude (panels | |
| 91 | b and e), and BSQ amplitude (panels c and f). The ratios were taken after taking the | |
| 92 | logarithm of the signal intensities of MH^+ at the right-hand side of the instrument setting | |
| 93 | (after the arrow) to that at the left-hand side of the instrument setting stated in the panel | |
| 94 | label; likewise, the fractional differences are the fractions of the MH^+ signal among the | |
| 95 | protonated, fragmented, and adduct signals under these two instrumental settings. | 20 |
| 96 | Figure S15. The dependence of the $[MH+H_2O]^+$ signals on RH for the VOCs studied. Panels | |
| 97 | a-f: the relative sensitivity was calculated as the slope (sensitivity) under high-RH | |
| 98 | conditions to that at the dry ($RH < 5\%$) condition. Panel g: the percent change of relative | |
| 99 | sensitivity per 10% RH increase. | 21 |
| 100 | Figure S16. The dependence of the $[MH-H_2O]^+$ signals on RH for the VOCs and OVOCs. | |
| 101 | Panels a-d: the relative sensitivity was calculated as the slope (sensitivity) under high-RH | |
| 102 | conditions to that at the dry ($RH < 5\%$) condition. Panel e: the percent change of relative | |
| 103 | sensitivity per 10% RH increase. | 22 |
| 104 | Figure S17. The dependence of the $[MH-C_xH_y]^+$ signals on RH for the VOCs and OVOCs | |
| 105 | tested at a concentration of ~ 12 ppbv. Panels a-e: the relative sensitivity was calculated as | |
| 106 | the slope (sensitivity) under high-RH conditions to that at the dry ($RH < 5\%$) condition. | |
| 107 | Panel f: the percent change of relative sensitivity per 10% RH increase. | 23 |

110 **Tables.**

111 **Table S1.** The details of instrument setting experiments.

| Varying setting | Vocus front (volt) | Vocus back (volt) | pressure (mbar) | E/N (Td) | BSQ (volt) | RF (volt) |
|-----------------|--------------------|-------------------|-----------------|-----------|------------|-----------|
| E | 300 to 700 | 34 | 2 | 48 to 142 | 260 | 500 |
| N | 500 | 34 | 1.5 to 3.5 | 57 to 133 | 260 | 500 |
| RF | 700 | 34 | 2 | 171 | 260 | 500 to 13 |
| BSQ | 700 | 34 | 2 | 171 | 300 to 50 | 500 |
| RF | 700 | 34 | 3.5 | 98 | 260 | 500 to 13 |
| BSQ | 700 | 34 | 3.5 | 98 | 300 to 50 | 500 |

133 Notes:

134 a, not available;

135 b, the specific percentage of fragment or adducted ion signals on all ion signals;

136 c, from gas standard cylinders I and II.

137 d, far less than 1 and closer to zero;

138 e, not determined due to overlapping signals.

Figures.

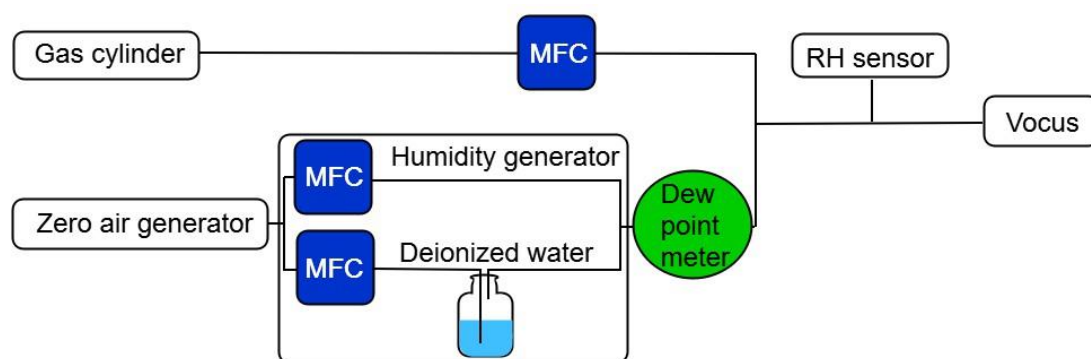

Figure S1. The diagram of the RH experimental setup. MFC: mass flow controller.

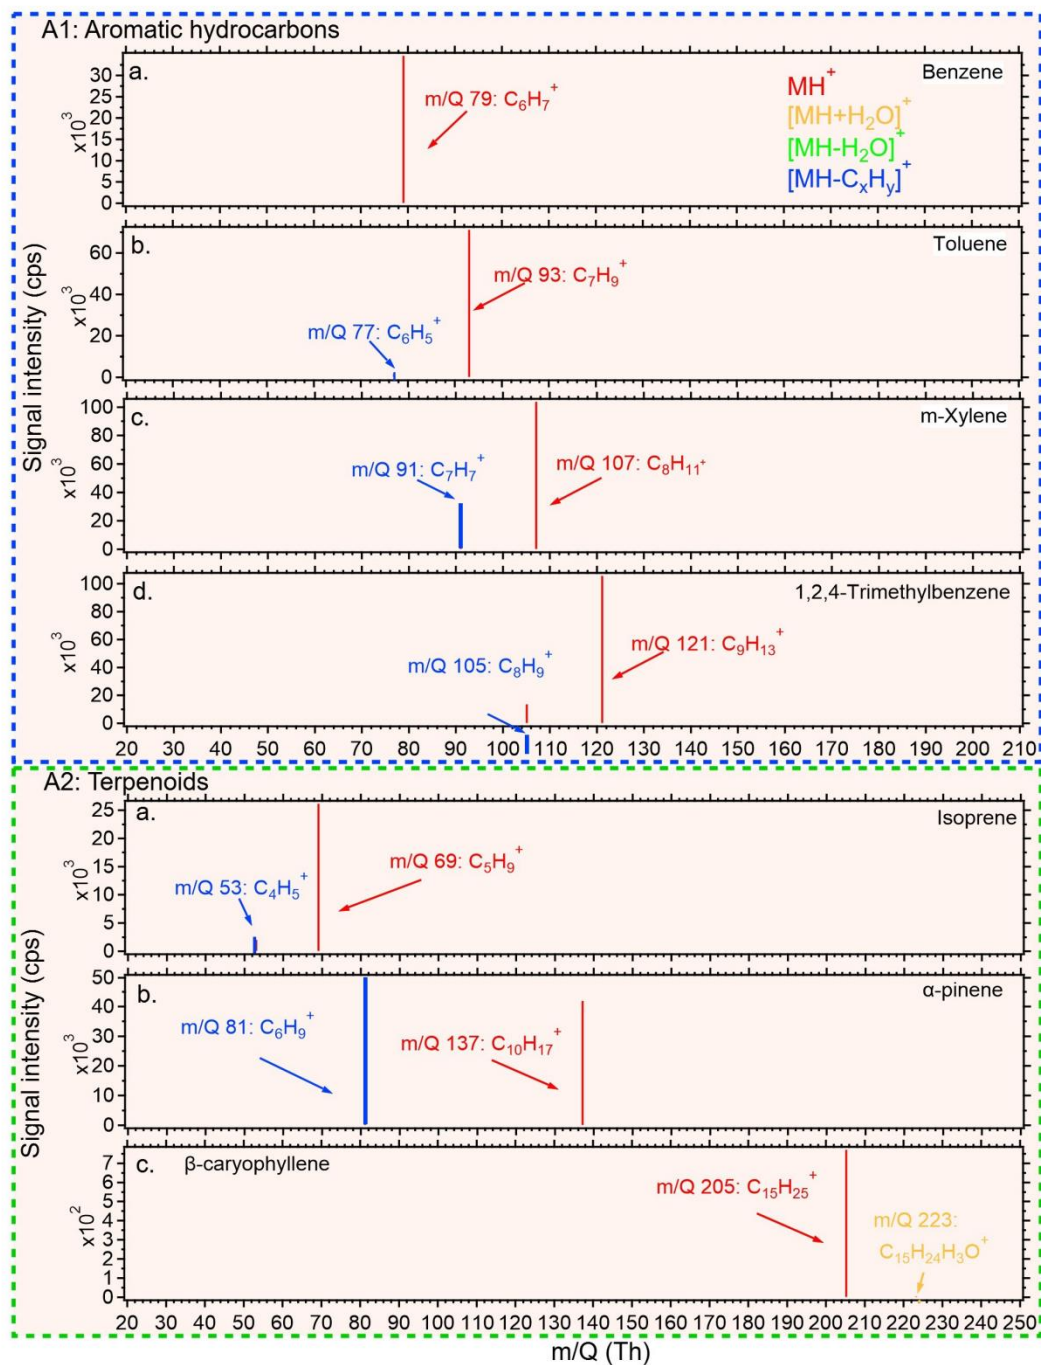

Figure S2. The mass spectra of aromatic hydrocarbons (benzene, toluene, m-xylene, and 1,2,4-trimethylbenene), and terpenoids (isoprene, α -pinene, and β -caryophyllene) in Vocus at a mixing ratio of ~ 12 ppbv (β -caryophyllene 1.2 ppbv).

Figure S3. The mass spectra of small aldehydes (formaldehyde and acetaldehyde), long-chain aldehydes (n-butanal, pentanal, and hexaldehyde), and ketones (acetone, and methyl ethyl ketone) in Vocus at a mixing ratio of ~ 12 ppbv.

Figure S4. The mass spectra of unsaturated aldehydes (acrolein and methacrolein), aromatic aldehydes (benzaldehyde and m-tolualdehyde), nitriles (acetonitrile and acrylonitrile), and methanol in Vocus at a mixing ratio of ~ 12 ppbv.

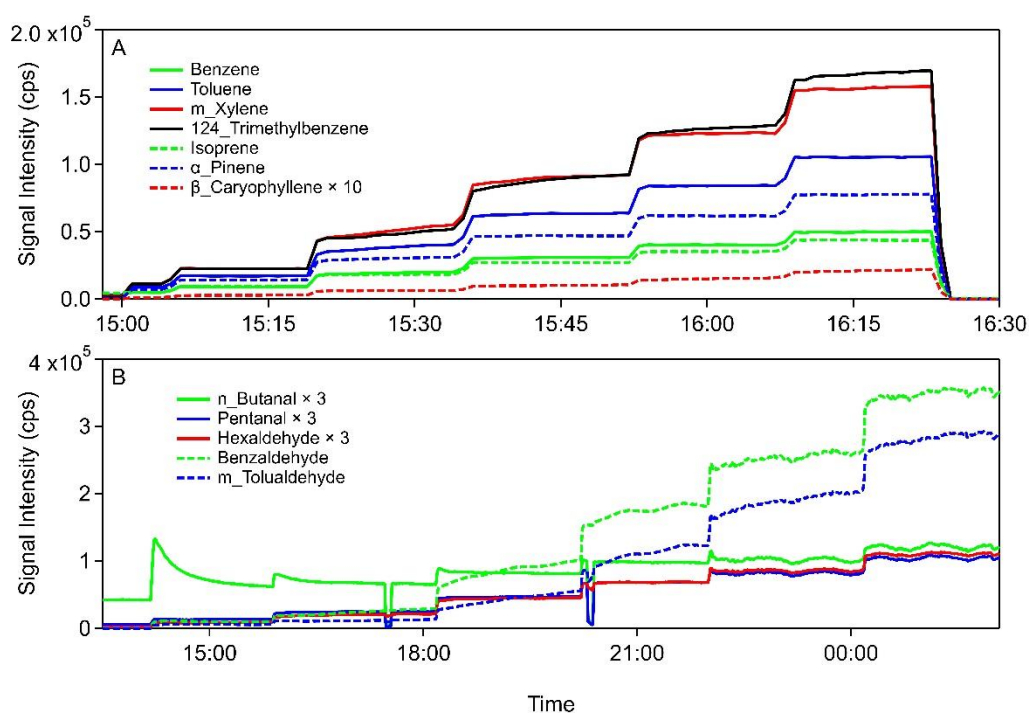

Figure S5. Time series of the protonated ion (MH^+) signals for selected (A) VOCs and (B) OVOCs as concentration varied from 0 to ~ 22 ppbv (~ 2 ppbv for β caryophyllene) under dry ($MH \sim 5\%$) conditions. Note the signals were magnified by 10 times for β -caryophyllene and 3 times for n-butanal, pentanal, and hexaldehyde.

Figure S6. Time series of the protonated ion (MH^+), adduct ions ($[\text{MH} + \text{H}_2\text{O}]^+$), and fragmented ions ($[\text{MH} - \text{H}_2\text{O}]^+$) and/or ($[\text{MH} - \text{C}_x\text{H}_y]^+$) signals for n-butanal, pentanal, and hexaldehyde. Note that the time in x axis is not continuous, with some periods with noisy signals cut off.

Figure S7. The signal intensities (panels a, b, and c, and panels g, h, and i) and fractions (panels d, e, and f, and panels j, k, and l) of protonated ion (MH^+), adduct ions ($[\text{MH} + \text{H}_2\text{O}]^+$), and fragmented ions ($[\text{MH} - \text{H}_2\text{O}]^+$ and $[\text{MH} - \text{C}_x\text{H}_y]^+$) for α -pinene as functions of E/N ratio (a, d, g, and j), RF amplitude (b, e, h, and k), and BSQ amplitude (c, f, i, and l). The difference between a/d and g/j is that the former fixed N ($p = 2.0$ mbar) and varied axial voltage (V) to change E/N ratio, while the latter fixed V (= 466 volts) and varied p (i.e., N) to change E/N ratio. The difference between b/e and h/k and between c/f and i/l is that the former was at $p = 2.0$ mbar while the latter $p = 3.5$ mbar. If not varied, RF amplitude was set at 500 volts and BSQ amplitude at 300 volts.

1,2,4-Trimethylbenzene

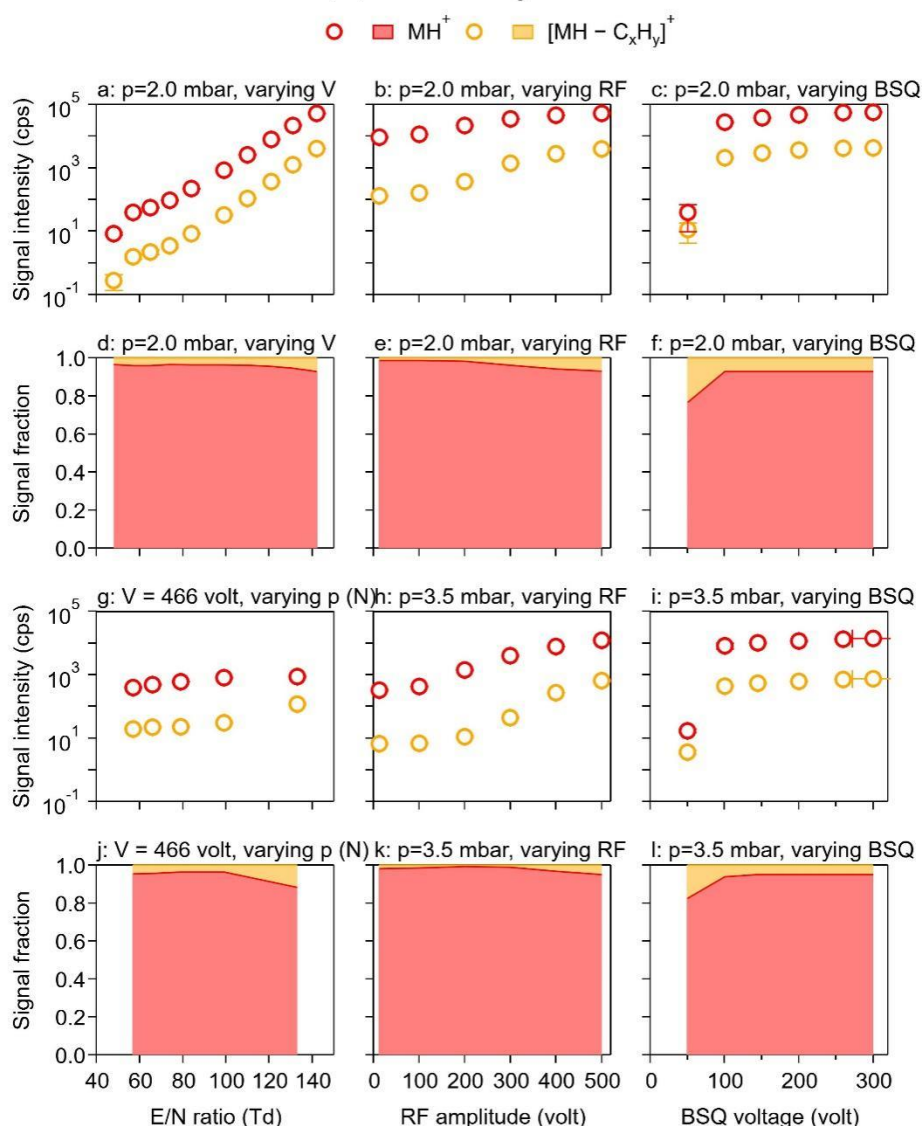

Figure S8. The signal intensities (panels a, b, and c, and panels g, h, and i) and fractions (panels d, e, and f, and panels j, k, and l) of protonated ion (MH^+), adduct ions ($[\text{MH} + \text{H}_2\text{O}]^+$), and fragmented ions ($[\text{MH} - \text{H}_2\text{O}]^+$ and $[\text{MH} - \text{C}_x\text{H}_y]^+$) for 1,2,4-trimethylbenzene as functions of E/N ratio (a, d, g, and j), RF amplitude (b, e, h, and k), and BSQ amplitude (c, f, i, and l). The difference between a/d and g/j is that the former fixed N ($p = 2.0$ mbar) and varied axial voltage (V) to change E/N ratio, while the latter fixed V (= 466 volts) and varied p (i.e., N) to change E/N ratio. The difference between b/e and h/k and between c/f and i/l is that the former was at $p = 2.0$ mbar while the latter $p = 3.5$ mbar. If not varied, RF amplitude was set at 500 volts and BSQ amplitude at 300 volts.

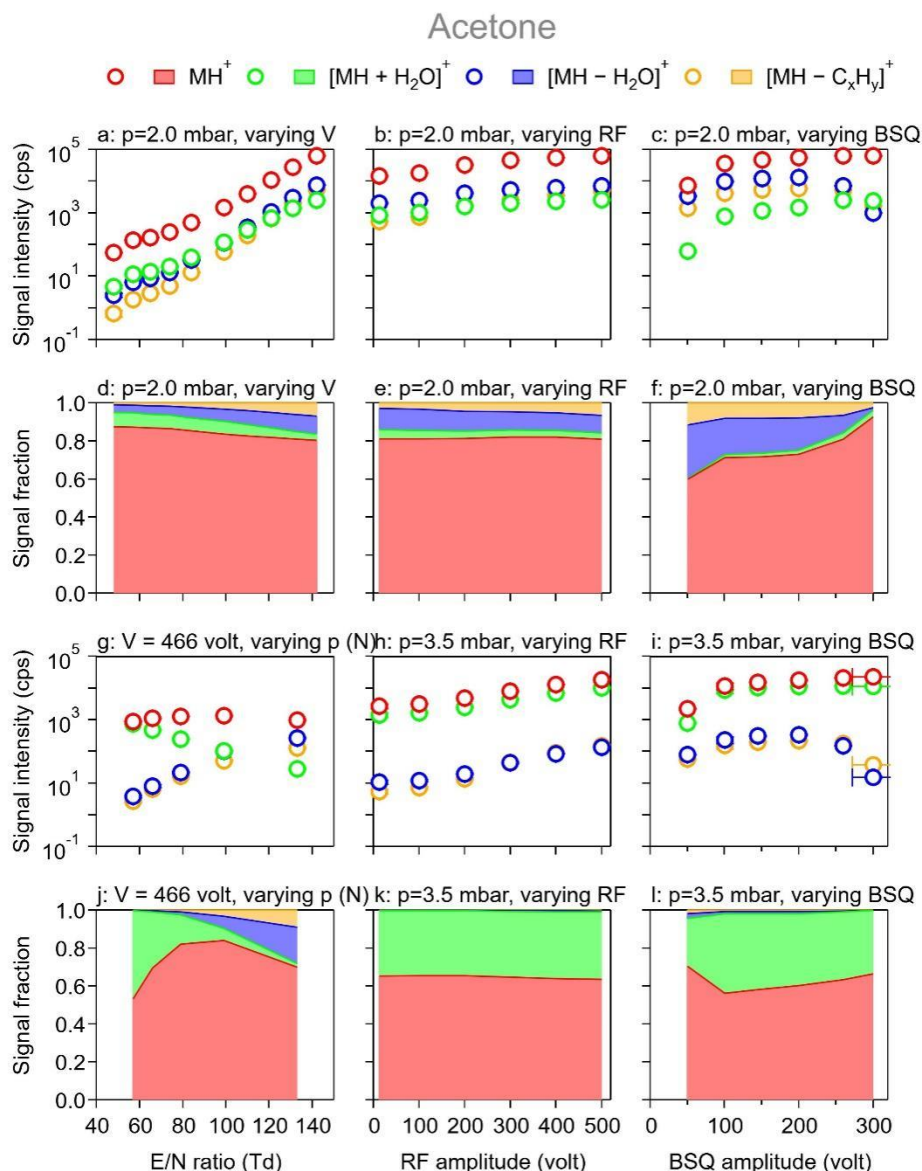

Figure S9. The signal intensities (panels a, b, and c, and panels g, h, and i) and fractions (panels d, e, and f, and panels j, k, and l) of protonated ion (MH^+), adduct ions ($[\text{MH} + \text{H}_2\text{O}]^+$), and fragmented ions ($[\text{MH} - \text{H}_2\text{O}]^+$ and $[\text{MH} - \text{C}_x\text{H}_y]^+$) for acetone as functions of E/N ratio (a, d, g, and j), RF amplitude (b, e, h, and k), and BSQ amplitude (c, f, i, and l). The difference between a/d and g/j is that the former fixed N ($p = 2.0$ mbar) and varied axial voltage (V) to change E/N ratio, while the latter fixed V (= 466 volts) and varied p (i.e., N) to change E/N ratio. The difference between b/e and h/k and between c/f and i/l is that the former was at $p = 2.0$ mbar while the latter $p = 3.5$ mbar. If not varied, RF amplitude was set at 500 volts and BSQ amplitude at 300 volts.

Figure S11. The ratio of α -pinene signals (MH^+ : 137 Th; $[MH - C_xH_y]^+$: 81 Th) to all ion signals. This was used to estimate the E/N ratio.

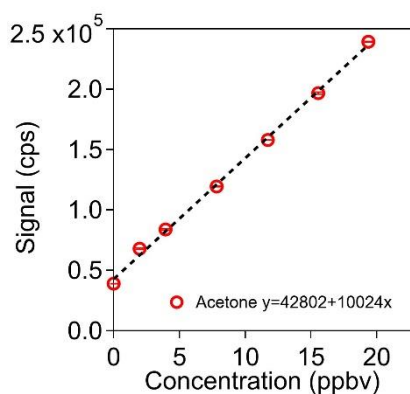

Figure S12. The sensitivity of acetone. An intercept above zero indicates a high background value.

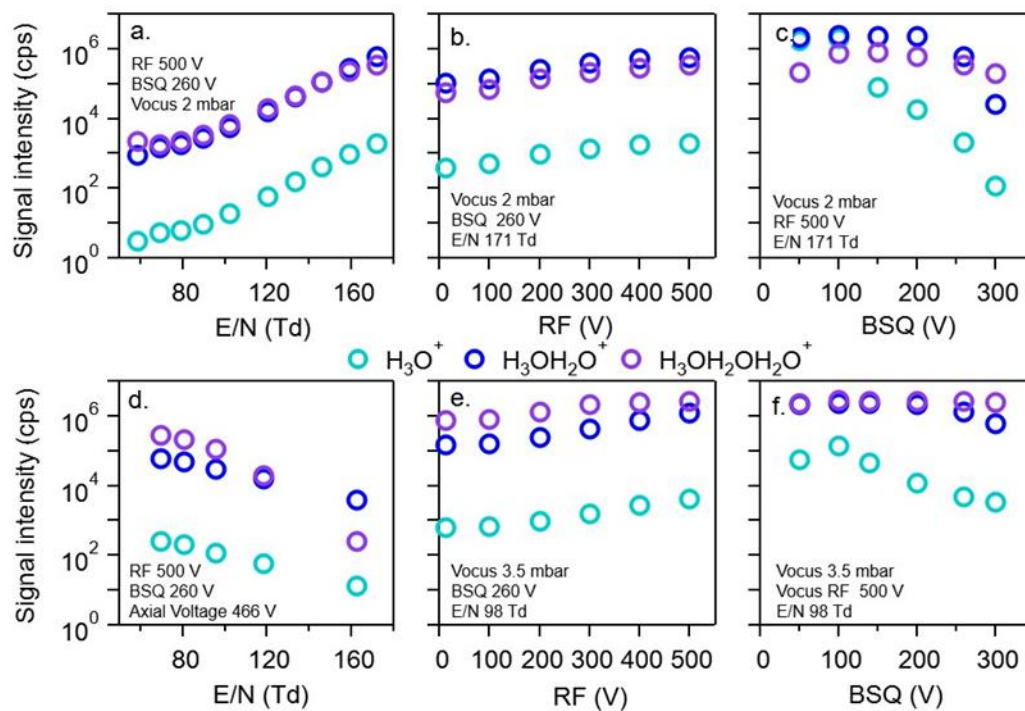

Figure S13. The signal intensities of H_3O^+ , $\text{H}_3\text{OH}_2\text{O}^+$, and $\text{H}_3\text{O}(\text{H}_2\text{O})_2^+$ as conditions varied as in Figures 3 in the main text and S14 below.

■ Aromatic hydrocarbons
 ■ Terpenoids
 ■ Small aldehydes
 ■ Long-chain aldehydes
 ■ Ketones
 ■ Unsaturated aldehydes
 ■ Aromatic aldehydes
 ■ Nitriles
 ■ Methanol

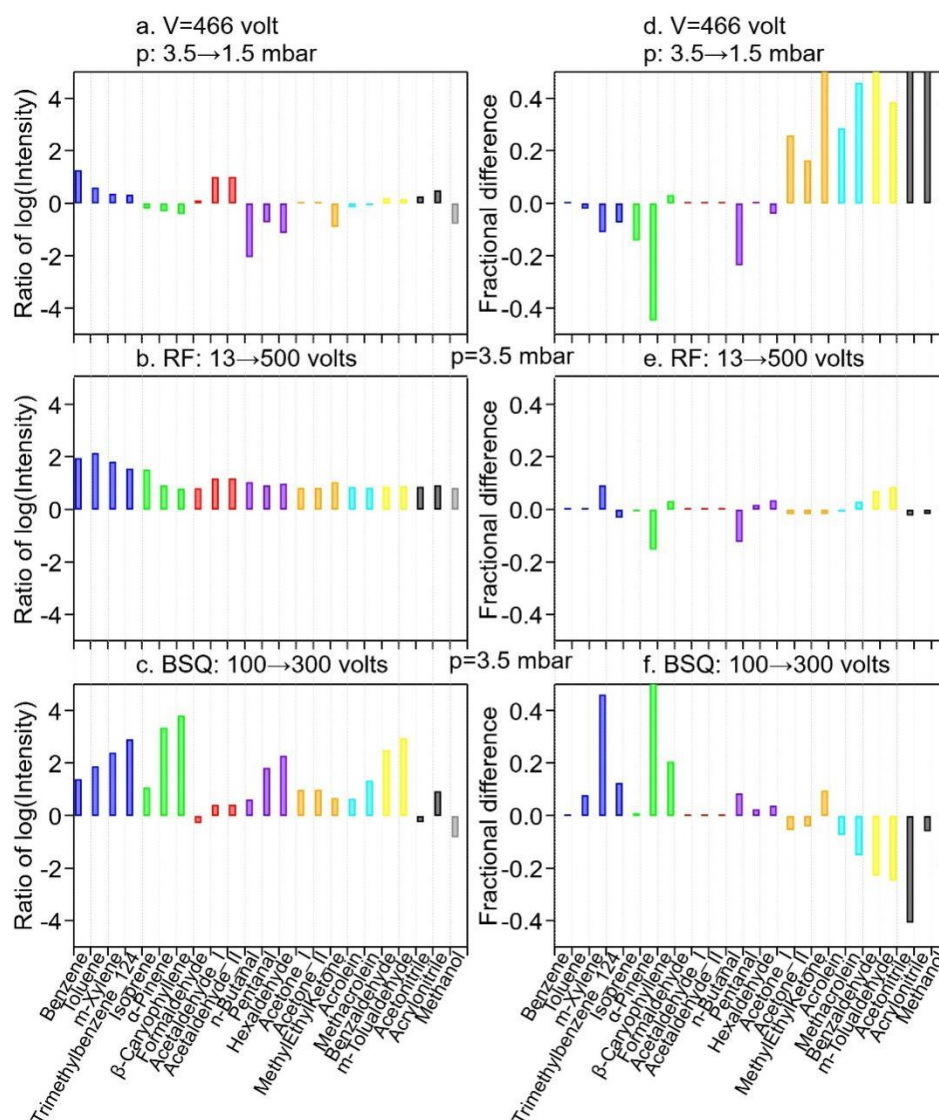

Figure S14. The ratio of the logarithm of intensity (panels a, b, and c) and the difference of fractional signal of the protonated ion (MH^+) among all ions (panels d, e, and f), when changing axial voltage (V) or FIMR pressure (p) (panels a and d), RF amplitude (panels b and e), and BSQ amplitude (panels c and f). The ratios were taken after taking the logarithm of the signal intensities of MH^+ at the right-hand side of the instrument setting (after the arrow) to that at the left-hand side of the instrument setting stated in the panel label; likewise, the fractional differences are the fractions of the MH^+ signal among the protonated, fragmented, and adduct signals under these two instrumental settings.

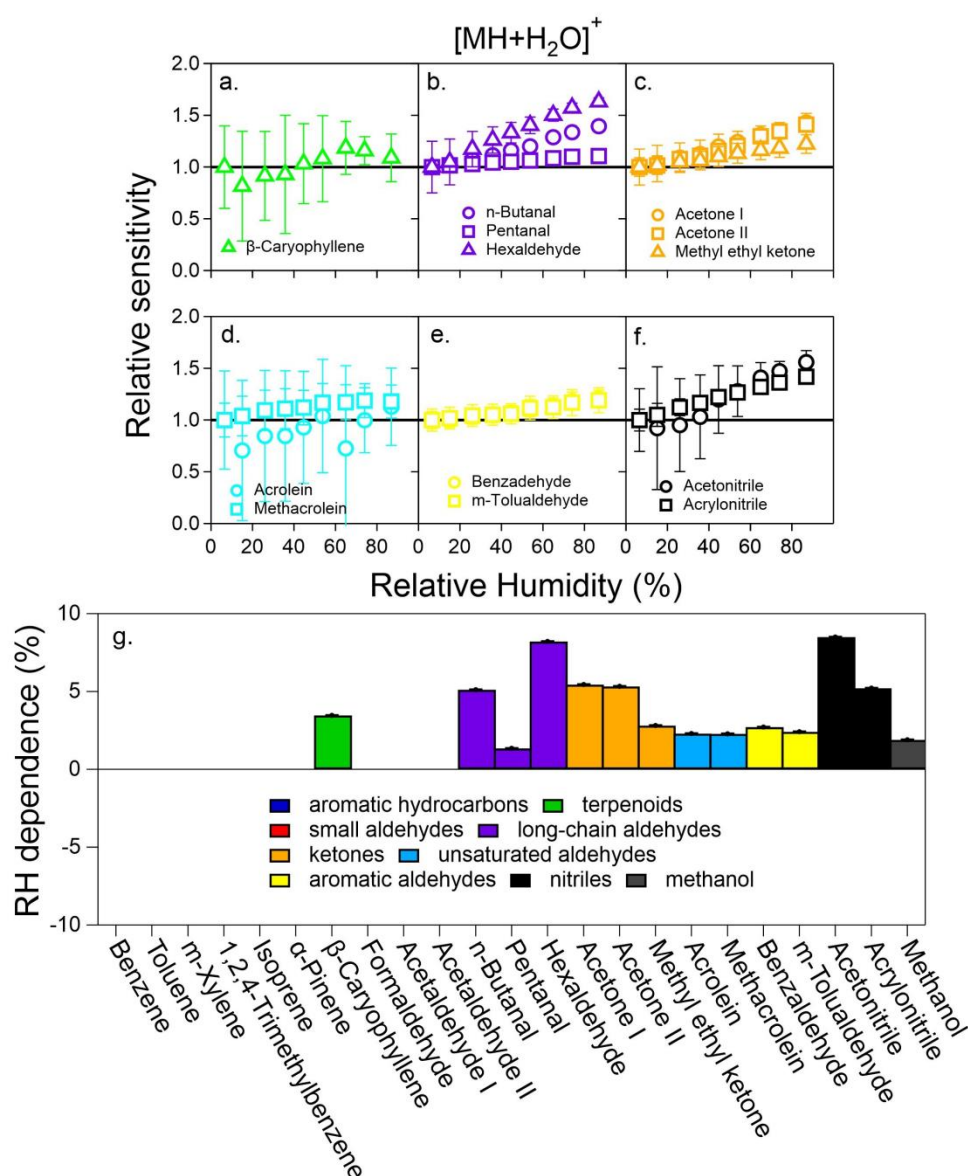

Figure S15. The dependence of the $[MH+H_2O]^+$ signals on RH for the VOCs studied. Panels a-f: the relative sensitivity was calculated as the slope (sensitivity) under high-RH conditions to that at the dry (RH<5%) condition. Panel g: the percent change of relative sensitivity per 10% RH increase.

Figure S16. The dependence of the $[MH-H_2O]^+$ signals on RH for the VOCs and OVOCs. Panels a-d: the relative sensitivity was calculated as the slope (sensitivity) under high-RH conditions to that at the dry (RH<5%) condition. Panel e: the percent change of relative sensitivity per 10% RH increase.

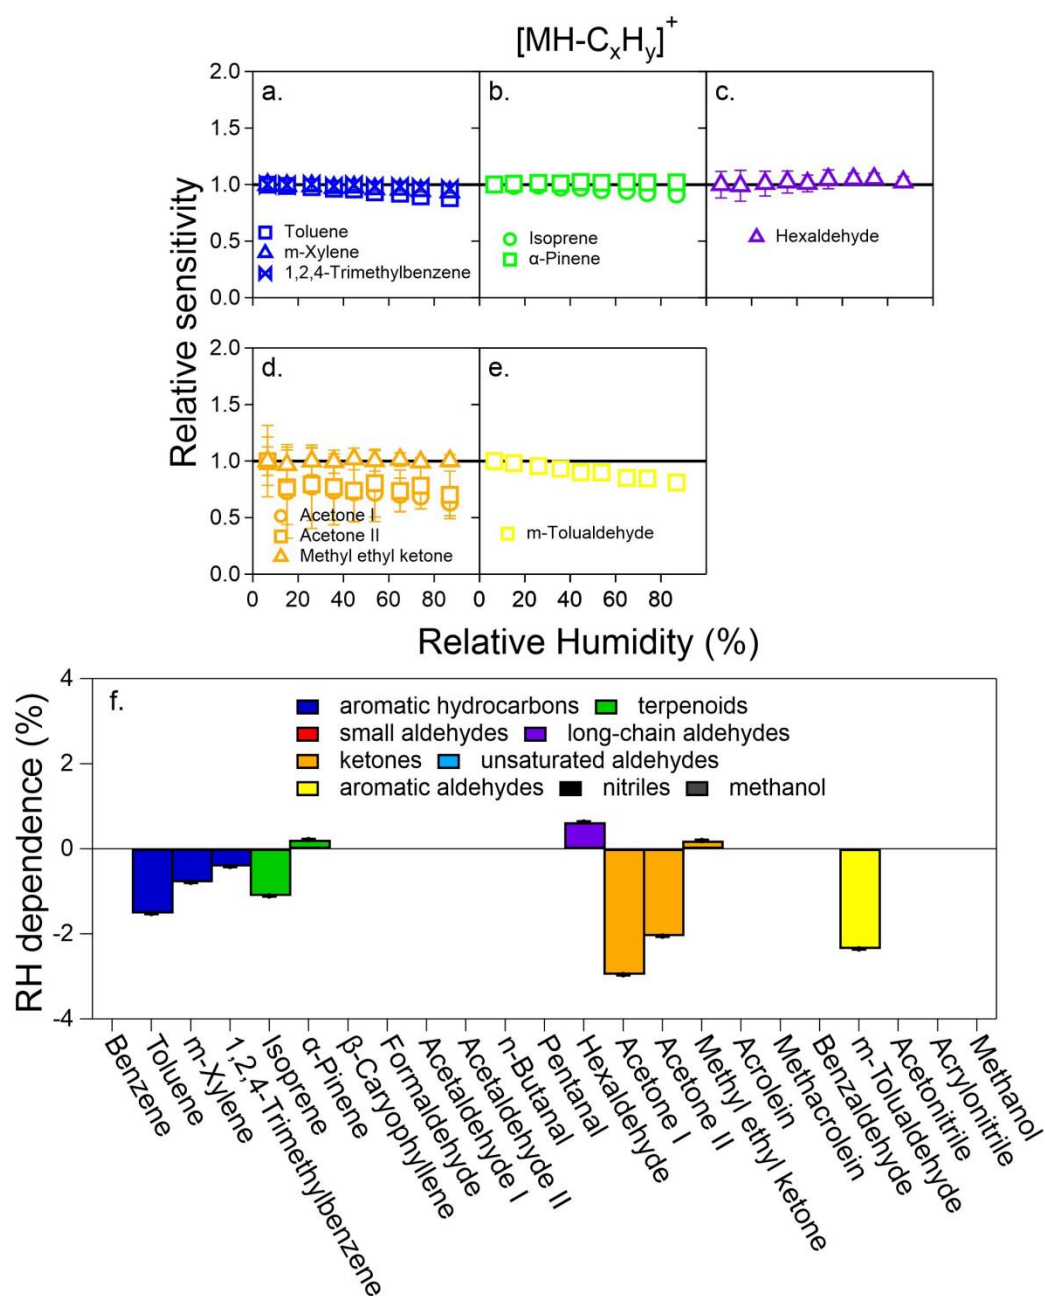

Figure S17. The dependence of the $[MH-C_xH_y]^+$ signals on RH for the VOCs and OVOCs tested at a concentration of ~ 12 ppbv. Panels a-e: the relative sensitivity was calculated as the slope (sensitivity) under high-RH conditions to that at the dry ($RH < 5\%$) condition. Panel f: the percent change of relative sensitivity per 10% RH increase.
