This is a very interesting paper paving a way towards a practical use of tandem mass spectrometry for analyses of SQT present in air.

It is good to see that only even electron (nonradical) ions are produced from protonated product ions but that both radical and nonradical ions are produced from the radical cations.

Is there any way the observed fragmentation could be rationalised with reference to the structures of the SQT molecules? It would be really useful to give a scheme with

structures and indicate which are the major neutral fragments lost in CID.

It really looks promising in the terms of potential for determining the identity of SQT from the in-situ data.
