S1 Chemical mechanism used to study the dependence of [CH₃O]/[CH₃O₂]₀ at the FAGE detection axis on the concentration of NO

The chemical mechanism assumed to be occurring within FAGE after adding NO ~ 25 mm before the CH₃O detection axis to convert CH₃O₂ into CH₃O is described in Table S1 and by Reactions (R3)–(R4) and (R10)–(R11) in the main text.

Table S1. Reactions and rate coefficients at 298 K, k_{298} (Atkinson et al., 2006), used in the numerical simulations described in Sect. 2.2 of the main text using the numerical integration package Kintecus (Ianni, 2002).

| Reaction ^a | k_{298} / molecule ⁻¹ cm ³ s ⁻¹ |
|--|--|
| (R3) $CH_3O_2 + NO \rightarrow CH_3O + NO_2$ | $7.7	imes10^{-12}$ |
| (R4) $CH_3O + O_2 \rightarrow CH_2O + HO_2$ | $1.9	imes10^{-15}$ |
| (R10) $CH_3O + NO \rightarrow CH_2O + HNO$ | $2.3	imes10^{-12}$ |
| (R11) $CH_3O + NO + M \rightarrow CH_3ONO + M$ | $2.2 	imes 10^{-12 b}$ |

^{*a*} The reactions are numbered to correspond to those in the main text $h \in A$ is the last $h \in A$ of T.

^{*b*} Calculated for $p_{\text{FAGE}} = 2.65$ Torr

S2 FAGE measurement of OH in the calibration flow tube in the absence/presence of CH₄

In order to calibrate FAGE for the sensitivity towards the detection of methyl peroxy radicals, CH_3O_2 , OH was generated in a flow tube by water photolysis at 184.9 nm in synthetic air and in the presence of excess methane. The 184.9 nm light was generated by a Hg Pen–Ray lamp. CH_3O_2 was produced by reactions (R1)–R(2) (the reactions are numbered to correspond to those in the main text).

$$OH + CH_4 \rightarrow CH_3 + H_2O$$

$$CH_3 + O_2 + M \rightarrow CH_3O_2 + M$$
(R1)
(R2)

where $M = N_2$ or O_2 .

OH was measured in the absence and in the presence of CH₄ to determine the conversion fraction of OH into CH₃O₂ for the relevant reaction time. The Hg lamp current was varied between 0–20 mA. Figure S1 shows an example of the OH signal with and without CH₄ added to the gas flow. For a typical concentration of CH₄, 5×10^{16} molecule cm⁻³, 0.96 ± 0.04 of OH was converted into CH₃O₂ for a reaction time of ~ 11 ms in average.

Figure S1. FAGE signal from OH radicals in the absence (until 300 s) and the presence (from 300 s) of 5×10^{16} molecule cm⁻³ CH₄ in the calibration flow tube obtained by flowing 82.5 sccm of CH₄ (main text). The air flow rate in the flow tube was 40 slm giving a reaction time of ~ 11 ms; the concentration of OH in the absence of CH₄ is 4.4×10^8 molecule cm⁻³, obtained by calibration.

S3 Methyl peroxy calibration using kinetics of the CH₃O₂ second-order decay

The FAGE instrument was coupled to HIRAC to sample the gas with a flow rate of about 3 slm at around 230 mm from the chamber wall. The temporal decays of the CH_3O_2 FAGE signal were generated by turning off the photolysis lamps and analyzed using Eq. (S1) (Eq. (6) in the main paper).

$$\frac{1}{(S_{\rm CH_3O_2})_t} = \frac{1}{(S_{\rm CH_3O_2})_0} + \frac{2 \cdot k_{\rm obs}t}{C_{\rm CH_3O_2}} \qquad \text{or} \qquad (S_{\rm CH_3O_2})_t = 1 / \left(\frac{1}{(S_{\rm CH_3O_2})_0} + \frac{2 \cdot k_{\rm obs}t}{C_{\rm CH_3O_2}}\right), \tag{S1}$$

In Eq. (S1) $(S_{CH3O2})_t$ and $(S_{CH3O2})_0$ are the signal at time t and t = 0, respectively. Eq. (S1) was fitted to the experimental decays (see Fig. S2) of S_{CH3O2} , fixing k_{obs} to the IUPAC recommendation, $k_{obs} = (4.8 \pm 1.1) \times 10^{-13}$ cm³ molecule⁻¹ s⁻¹ (Atkinson et al., 2006) and $(S_{CH3O2})_0$ to the mean value of the signal before the lamps were turned off to determine the FAGE sensitivity for CH₃O₂, c_{CH3O2} . Eighteen independent determinations were performed in total with the results presented in Table S2.

Table S2. FAGE sensitivity factors and initial CH₃O₂ concentrations in the HIRAC experiments. Equation (S1) was fitted to the temporal decays of the CH₃O₂ signal to extract C_{CH3O2} and the initial signal, (S_{CH3O2})₀, which were then used to determine the initial CH₃O₂ concentrations by using [CH₃O₂]₀ = (S_{CH3O2})₀/ C_{CH3O2} .

S4 Comparison of CH₃O₂ temporal decays for different [CH₃O₂]₀

Figure S2 shows the CH₃O₂ FAGE signal decays together with second-order fits recorded for three different $[CH_3O_2]_0$ in HIRAC. The initial signals, $(S_{CH3O2})_0$, were rescaled to start the decays from the same value, $(S'_{CH3O2})_0$ (Eq. (S2)), and show that the temporal decays slow down with the decrease in $[CH_3O_2]_0$ as expected from the dependence of the rate of second–order decays upon $[CH_3O_2]$. Equation (S3) was then fitted to the data shown in Fig. S2 to extract the FAGE sensitivity factor, C_{CH3O2} .

$$(S'_{CH_3O_2})_0 = f \cdot (S_{CH_3O_2})_0,$$
(S2)

$$(S'_{CH_3O_2})_t = 1 / \left(\frac{1}{(S'_{CH_3O_2})_0} + \frac{2 \cdot k_{obs}t}{f \cdot C_{CH_3O_2}} \right),$$
(S3)

where *f* is the rescale factor.

Figure S2. Typical temporal decays of the CH₃O₂ FAGE signal recorded in HIRAC. The experimental data were rescaled to start the decays from the same value, $(S'_{CH_3O_2})_0 = f \cdot (S_{CH_3O_2})_0$, where *f* is the rescale factor. Equation (S3) was fitted to data to extract the FAGE sensitivity factor, $C_{CH_3O_2}$ (counts s⁻¹ mW⁻¹ cm³ molecule⁻¹): $(7.5 \pm 0.1) \times 10^{-10}$ (black line), $(7.3 \pm 0.3) \times 10^{-10}$ (red line) and $(4.5 \pm 0.1) \times 10^{-10}$ (blue line), which was then used to determine the initial CH₃O₂ concentrations presented in the legend by using [CH₃O₂]₀ = ($S_{CH_3O_2}$)₀/ $C_{CH_3O_2}$.

S5 Fit of simulated decays of [CH₃O₂] as a function of time

The CH₃O₂ self-reaction occurs through two different channels, (R6.a) and (R6.b) (main text):

$$CH_{3}O_{2} + CH_{3}O_{2} \rightarrow CH_{3}OH + CH_{2}O + O_{2}$$

$$CH_{3}O_{2} + CH_{3}O_{2} \rightarrow CH_{3}O + CH_{3}O + O_{2}$$

$$(R6.b)$$

The observed rate coefficient describing the decay of $[CH_3O_2]$ vs. time, k_{obs} , is larger than the secondorder rate coefficient of just the CH₃O₂ self-reaction, k_6 and given by Eq. (S4) (Eq. (7) in the main paper) (Sander and Watson, 1981;Lightfoot et al., 1990). $k_{obs} = k_6 \cdot (1 + r_{6.b})$

where $r_{6.b}$ is the branching ratio for the reaction channel R6.b. The IUPAC preferred value is $k_{obs} = (4.8 \pm 1.1) \times 10^{-13}$ cm³ molecule⁻¹ s⁻¹.

In order to check the validity of Eq. (S4) in the presence of HO₂ removal by self-reaction and wallloss, numerical simulations were performed to generate CH₃O₂ decays using a system incorporating the chemistry described by Reactions (R4), (R6), R(13) and R(14) shown in the main paper and Table S3 below and a heterogeneous loss of HO₂ ($k_{loss(HO2)}$). The rate coefficients were sourced from the IUPAC recommended values at 298 K (Table S3) and $k_{loss(HO2)}$ was varied. The simulated temporal decays of CH₃O₂ were analysed using Eq. (S5) and gave an average observed rate coefficient of $k_{obs} = 4.7 \times 10^{-13}$ cm³ molecule⁻¹ s⁻¹, which is only 2 % lower than the IUPAC recommendation (*vide supra*), for $k_{loss(HO2)}$ in the range 0.01–0.10 s⁻¹ and, hence confirmed the applicability of Eq. (S4).

$$\left[\mathrm{CH}_{3}\mathrm{O}_{2}\right]_{t} = 1 / \left(\frac{1}{\left[\mathrm{CH}_{3}\mathrm{O}_{2}\right]_{0}} + \frac{2 \cdot k_{\mathrm{obs}}t}{C_{\mathrm{CH}_{3}\mathrm{O}_{2}}}\right),\tag{S5}$$

A typical simulated decay of CH₃O₂, and the fit to the simulation using Eq. (S5), is shown in Fig. S3.

Figure S3. Simulated decay of $[CH_3O_2]$ against time (black circles), using the reactions and the rate coefficients listed in Table S3 and $k_{loss(HO2)} = 0.03 \text{ s}^{-1}$, and the fit to the simulation using Eq. (S5) (red line) to determine $k_{obs} = 4.7 \times 10^{-13} \text{ cm}^3$ molecule⁻¹ s⁻¹.

Table S3. Reactions and rate coefficients used in the numerical simulations of the CH_3O_2 temporal decays using the Kintecus package (Ianni, 2002). The rate coefficients are sourced from IUPAC preferred values at 298 K, k_{298} , (Atkinson et al., 2006).

S6 Chemical mechanism used in numerical simulations to fit the experimental time-profile of the CH₃O concentration shown in Figure 8 of the main paper

In the experiments carried out to measure the concentration of CH₃O generated by the CH₃O₂ self– reaction (Section 3.3 of the main paper) the chamber was filled with high purity N₂. Oxygen was purposely delivered in trace amounts by the incomplete purging of the several meter long pipe delivering N₂. The Cl₂ concentration used in these experiments was 5.6×10^{15} molecule cm⁻³ and hence was 1–2 orders of magnitude higher than [Cl₂]₀ used in the CH₃O₂ calibration experiments (0.3–2.1 × 10^{14} molecule cm⁻³). Cl atoms were generated by Cl₂ photolysis using black lamps (peak emission wavelength of ~ 360 nm) for the entire experiment to react quickly with CH₄ present in high excess, [CH₄]₀ = 4.50 × 10¹⁷ molecule cm⁻³. Numerical simulations carried out using the chemistry system described in Table S5 (*vide infra*) showed that [Cl] peaked at ~ 2 × 10⁸ molecule cm⁻³ several seconds after starting the experiment (Fig. S5b) followed by a gradual decay.

The experimental temporal profile of CH₃O is shown in Fig. 8 in the main paper and Fig. S4 below. By floating the O₂ concentration until a best–fit was obtained to the experimental data ($r^2 = 0.85$), the numerical simulations determined that the concentration of O₂ in the chamber was (5.4 ± 0.6) × 10¹⁵ molecule cm⁻³, i.e. around 0.02 % relative to N₂. In the numerical simulations the heterogeneous wall–loss of HO₂ was estimated to be 10⁻² s⁻¹ (Winiberg et al., 2015), with the same value assumed for CH₃O, and the heterogeneous loss of CH₃O₂ was estimated to be 10⁻³ s⁻¹ (see main text). The returned best–fit [O₂] did not change by increasing the wall–losses of HO₂, CH₃O and CH₃O₂ by one order of magnitude. Including a heterogeneous removal of Cl atom in the range of (0.001–1) s⁻¹ in the model did not change the result of the numerical simulations as the Cl wall–loss could not compete with the Cl + CH₄ reaction; the pseudo–first–order rate coefficient k'_{CH4+Cl} was ~ 4.5 × 10⁴ s⁻¹ during the experiment. The wall– losses of the other species were considered negligible during the 2 min time of the experiment in accordance with previous measurements (Winiberg et al., 2016).

Figure S4. Concentration of CH₃O as a function of time in HIRAC: red points are the experimental data and black points are generated by a numerical simulation. CH₃O radicals were formed as a product of the self-reaction of CH₃O₂ species at 295 K and 1000 mbar of N₂, with CH₃O₂ generated by the reaction of Cl atoms with CH₄, with the HIRAC black lamps being turned on at time zero. Oxygen was present in trace amounts, determined to be $(5.4 \pm 0.6) \times 10^{15}$ molecule cm⁻³ from the simulations fit to the experimental data.

The numerical simulations took into account the increase in intensity of the lamps output during the experiment (Winiberg et al., 2016). In order to numerically simulate the Cl concentration the photolysis rate of Cl₂, *j*(Cl₂), has been determined by performing separate experiments using the black lamps to simultaneously monitor the decay of CH₂O and the rise of CO during the Cl + CH₂O reaction by using *in situ* FTIR absorption spectroscopy (Glowacki et al., 2007). Numerical simulations have been performed using the reaction rate coefficients from IUPAC (Atkinson et al., 2006) (Table S4) to determine that $j(Cl_2) = (3.8 \pm 1.1) \times 10^{-4} \text{ s}^{-1}$. The result is to the same as the value found previously (Winiberg et al., 2016), $(3.8 \pm 1.4) \times 10^{-4} \text{ s}^{-1}$, during HIRAC experiments to study the HO₂ + CH₃C(O)O₂ reaction.

For the numerically simulated concentration of CH₃, of about 6×10^8 molecule cm⁻³ (Fig. S5c) and the reported rate coefficient for the Cl₂ + CH₃ reaction, $k_{CH_3 + Cl_2} = 1.5 \times 10^{-12}$ molecule⁻¹ cm³ s⁻¹, (Eskola et al., 2008) the removal of Cl₂ was dominated by the reaction with CH₃. The Cl₂ + CH₃ reaction recycled a Cl atom, which in turn reacted with CH₄ to regenerate more CH₃ radicals leading to the propagation of the Cl – CH₃ chain reaction and increasing the consumption rate of Cl₂. The removal of Cl_2 by the chain reaction resulted in a relatively sharp decrease of the peak [CH₃O], of about 50 % in 2 min (Fig. S4).

Table S4. Reactions and rate coefficients used in the numerical simulations of the time evolution of the concentrations of CH₂O and CO generated in the CH₂O/Cl₂/N₂/O₂ system in HIRAC using the numerical integration package Kintecus to determine j(Cl₂) (Ianni, 2002). The rate coefficients are sourced from the IUPAC preferred values at 298 K, k_{298} , (Atkinson et al., 2006).

| Reaction | k_{298} / s ⁻¹ or molecule ⁻¹ cm ³ s ⁻¹ | |
|--|---|---|
| $Cl_2 + h\nu \rightarrow 2Cl$ | $3.8 \times 10^{-4} = j(\text{Cl}_2)$ | а |
| $CH_2O + Cl \rightarrow CHO + HCl$ | $7.2 	imes 10^{-11}$ | |
| $CHO + O_2 \rightarrow HO_2 + CO$ | 5.1×10^{-12} | |
| $HO_2 + HO_2 \rightarrow H_2O_2 + O_2$ | $1.6 	imes 10^{-12}$ | |
