Abstract. Precise monitoring of changes in atmospheric O₂ levels was implemented by preparing primary standard mixtures with less than 1 $\mu\text{mol mol}^{-1}$ standard uncertainty for O₂ molar fractions. In this study, these mixtures were crafted in 10 L high-pressure aluminium alloy cylinders using a gravimetric method in which unknown uncertainty factors were theoretically determined and subsequently reduced. Molar fractions of the constituents (CO₂, Ar, O₂, and N₂) in the primary standard mixtures were mainly resolved using masses of the respective source gases (CO₂, Ar, O₂, and N₂) that had been filled into the cylinders. To precisely determine the masses of the source gases, the difference in mass of the cylinder before and after filling the respective source gas was calculated by compared with an almost identical reference cylinder. Although the masses of the cylinders filled with source gas with respect to the reference cylinder tended to deviate in relation to temperature differences between the source gas filled cylinder and surrounding air, the degree of the deviation could be efficiently reduced by measuring the two cylinders at the exact same temperature. The standard uncertainty for the cylinder mass obtained in our weighing system was determined to be 0.82 mg. The standard uncertainties for the O₂ molar fractions in the primary standard mixtures ranged from 0.7 $\mu\text{mol mol}^{-1}$ to 0.8 $\mu\text{mol mol}^{-1}$. Based on the primary standard mixtures, the annual average molar fractions of atmospheric O₂ and Ar in 2015 at Hateruma Island, Japan, were found to be $209339.1 \pm 1.1 \mu\text{mol mol}^{-1}$ and $9334.4 \pm 0.7 \mu\text{mol mol}^{-1}$, respectively. The molar fraction for atmospheric Ar was in agreement with previous reports.

1 Introduction

Observation of atmospheric O₂ molar fractions provides important information about the global carbon cycle (Keeling and Shertz, 1992; Bender et al., 1996; Keeling et al., 1996, 1998a; Stephens et al., 1998; Battle et al., 2000; Manning and Keeling, 2006). For example, long-term observation allows the estimation of land biotics and oceanic CO₂ uptake (Manning and Keeling, 2006; Tohjima et al., 2008; Ishidoya et al., 2012a, 2012b). Various measurement techniques have been developed for this purpose, including the utilization of interferometry (Keeling et al., 1998b), mass spectrometry (Bender et al., 1994; Ishidoya et al., 2003; Ishidoya and Murayama, 2014), a paramagnetic technique (Manning et al., 1999; Aoki et al., 2018; Ishidoya et al., 2017), a vacuum-ultraviolet absorption technique (Stephens et al., 2003), gas chromatography (Tohjima, 2000), and a method utilizing fuel cells (Stephens et al., 2007; Goto et al., 2013). In all these cases, calibration using standard mixtures is required to precisely determine the relationship between the analysis output and O₂ molar fractions obtained.

Molar fractions of O₂ and Ar are commonly expressed as functions of the O₂/N₂ and Ar/N₂ ratios relative to an arbitrary reference (Keeling and Shertz, 1992; Keeling et al., 2004) in per meg (one per meg is equal to 1×10^{-6}).

1
2
$$\delta(\text{O}_2/\text{N}_2) = \frac{[n(\text{O}_2)/n(\text{N}_2)]_{\text{sam}}}{[n(\text{O}_2)/n(\text{N}_2)]_{\text{ref}}} - 1 \quad (1)$$

3
4
$$\delta(\text{Ar}/\text{N}_2) = \frac{[n(\text{Ar})/n(\text{N}_2)]_{\text{sam}}}{[n(\text{Ar})/n(\text{N}_2)]_{\text{ref}}} - 1 \quad (2)$$

5
6
7
8 In these equations, n depicts the amount of each substance, and the subscripts “sam” and “ref” refer to sample air and reference
9 air, respectively. As the O_2 and Ar molar fractions in air are 20.946% and 0.943%, respectively, a respective change of 4.8
10 per meg and 107 per meg in $\delta(\text{O}_2/\text{N}_2)$ and $\delta(\text{Ar}/\text{N}_2)$ corresponds to a change of $1 \mu\text{mol mol}^{-1}$ in molar fractions of O_2 and Ar.
11 Reported peak-to-peak amplitudes of seasonal cycles and trends in atmospheric $\delta(\text{O}_2/\text{N}_2)$ were within the range of 50 – 150
12 per meg ($10 - 30 \mu\text{mol mol}^{-1}$ for O_2 molar fractions) and -20 per meg yr^{-1} ($-4 \mu\text{mol mol}^{-1} \text{yr}^{-1}$ for O_2 molar fractions)
13 (Keeling et al., 1993; Battle et al., 2000; Van der Laan–Luijkx et al., 2013). To monitor these slight variations, the development
14 of primary standard mixtures with standard uncertainty of less than 5 per meg for O_2/N_2 ratios ($1 \mu\text{mol mol}^{-1}$ for O_2 molar
15 fractions) or less (Keeling et al., 1993; WMO, 2016) is required. In this study, the primary O_2 standard mixture with the
16 recommended uncertainty of 5 per meg ($1 \mu\text{mol mol}^{-1}$) or less is hereafter referred to as a “highly precise O_2 standard mixture
17 (HPO)”.

18 In general, standard mixtures need to be prepared in which molar fractions of the greenhouse gas species, such as CO_2 , CH_4 ,
19 and N_2O , are stable enough during the observation period to enable monitoring of long-term changes in atmospheric molar
20 fractions of their species. For this purpose, it is indispensable to establish methods for determining absolute molar fractions
21 of greenhouse gases in the standard mixtures with required precision. Approved primary standard mixtures exist for CO_2 , CH_4 ,
22 and N_2O , prepared by manometry (Zhao et al., 1997) or gravimetry (Tanaka et al., 1983; Matsueda et al., 2004; Dlugokencky
23 et al., 2005; Hall et al., 2007). However, preparing an HPO is challenging since it is necessary to prepare it with the relative
24 uncertainty of less than one-fifth of that for the CO_2 molar fraction in the CO_2 standard mixture. Since there is no common
25 scale for atmospheric O_2 observation, such as the ratio of O_2/N_2 determined using HPOs, each laboratory has employed
26 reference air determined using its own reference scale instead of a universal scale. This reference scale is determined based
27 on O_2/N_2 ratios in primary standard mixtures filled in high-pressure cylinders and is considered to be sufficiently stable during
28 the observation period (e.g. Keeling et al., 1998b; Tohjima et al., 2008; Ishidoya et al., 2012b). However, there are many
29 deterioration risks of the O_2/N_2 ratio in aluminium cylinders used for reference air and the primary standard mixtures. these
30 include fractionations of O_2 and N_2 induced by pressure, temperature and water vapor gradients (Keeling et al., 1998b),
31 adsorption/desorption of the constituents on the inner surface (Leuenberger et al., 2015), and permeation/leakage of the
32 constituents from/through the valve (Sturm et al., 2004; Keeling et al., 2007). In order to avoid these risks, the cylinders are
33 handled in accordance to certain best practices, including orienting cylinders horizontally to minimize thermal and
34 gravitational fractionation (Keeling, et al. 2007, Leuenberger, et al., 2015).

35 Although causes behind the fractionation should be sufficiently described by now, the effects of permeation and
36 adsorption/desorption have not been completely understood in the long-term scale. To enable comparison of O_2/N_2 values

1 reported based on reference air with the difference scale directly, an independent development of primary standard mixtures
2 with standard uncertainty of 5 per meg ($1 \mu\text{mol mol}^{-1}$) or less is needed. In a pioneering study, Tohjima et al. (2005) first
3 prepared primary standard mixtures for the atmospheric O_2 measurement based on a gravimetric method. The standard
4 uncertainties for the O_2/N_2 ratio (the O_2 molar fraction) were noted at 15.5 per meg ($2.9 \mu\text{mol mol}^{-1}$), which was larger than
5 the required standard uncertainty of 5 per meg ($1 \mu\text{mol mol}^{-1}$) or less. Since the $2.9 \mu\text{mol mol}^{-1}$ standard uncertainty recorded
6 by Tohjima et al. (2005) was significantly larger than the gravimetrically expected value of $1.6 \mu\text{mol mol}^{-1}$, it was suggested
7 that there are unknown factors exerting influence on the mass results of cylinders.

8 Taking these facts into consideration, in this study we set out to develop a new gravimetric method to prepare an HPO by
9 scientifically understanding the unknown uncertainty factors in the cylinder mass measurement. Our laboratory has built upon
10 the weighing system proposed by Matsumoto et al. (2004), in which gravimetry was used to prepare standard mixtures.
11 Although this system allows accurate mass measurements with a standard uncertainty of 2.6 mg, this proves insufficient to
12 prepare an HPO. A new mass comparator with better repeatability was recently introduced to the weighing system. In the
13 present study, we theoretically identified the unknown factors and presented an improved means of minimizing them. The
14 standard uncertainties for molar fractions of all constituents in HPOs, prepared using these improved means, are discussed.
15 Moreover, the molar fractions of all constituents in the HPOs were validated by comparing the gravimetric value with the
16 measured values of CO_2 mole fraction, Ar/N_2 ratio, and O_2/N_2 ratio. In order to validate the scale of O_2/N_2 ratio at the National
17 Institute of Advanced Industrial Science and Technology (AIST) determined using the HPOs prepared in this study, the annual
18 average of O_2/N_2 ratios in 2015 at Hateruma Island ($24^\circ 03' \text{N}$, $123^\circ 49' \text{E}$, Japan) obtained from our measurements of air samples
19 were preliminarily compared with the annual average of O_2/N_2 ratios in 2015 at Hateruma Island on the NIES scale determined
20 by Tohjima et al. (NIES). Additionally, the molar fractions for atmospheric Ar and O_2 in air samples were determined using
21 the HPOs and compared with previously reported values.

22 **2 Materials and Methods**

23 **2.1 Preparation of the highly precise O_2 standard mixtures**

24 Eleven HPOs were prepared in 10 L aluminium alloy cylinders (Luxfer Gas Cylinders, UK), with a diaphragm valve (G-55,
25 Hamai Industries Limited, Japan) with poly(chlorotrifluoroethylene) (PCTFE) as sealant in accordance with ISO 6142-1:2015.
26 Pure CO_2 (>99.998 %, Nippon Ekitan Corporation, Japan), pure Ar (G1-Grade, 99.9999 %, Japan Fine Products, Japan), pure
27 O_2 (G1-Grade, 99.99995 %, Japan Fine Products, Japan), and pure N_2 (G1-Grade, 99.99995 %, Japan Fine Products, Japan)
28 were used as source gases to prepare the HPOs. The value of $\delta^{13}\text{C}$ in pure CO_2 (which was adjusted to the atmospheric level)
29 was -8.92‰ relative to Vienna Pee Dee Belemnite (VPDB). Impurities in the source gases were identified and quantified
30 using gas chromatography with a thermal conductivity detector for N_2 , O_2 , CH_4 and H_2 in pure CO_2 , and gas chromatography
31 with a mass spectrometer for O_2 and Ar in pure N_2 and N_2 in pure O_2 . A Fourier transform infrared spectrometer was used for
32 detection of CO_2 , CH_4 and CO in pure N_2 , O_2 , and Ar. A galvanic cell-type O_2 analyser was employed to quantify O_2 in pure
33 Ar. A capacitance-type moisture meter measured H_2O in pure CO_2 , and a cavity ring-down-type moisture meter measured
34 H_2O in pure N_2 , O_2 and Ar.

35 Primarily, standard mixtures of CO_2 in Ar were prepared by combining pure CO_2 and pure Ar using a gravimetric method.
36 The molar ratios of CO_2 to Ar were close to the atmospheric molar ratio of CO_2 ($400 \mu\text{mol mol}^{-1}$ or $420 \mu\text{mol mol}^{-1}$) to Ar

1 (9340 $\mu\text{mol mol}^{-1}$). The 10 L aluminium cylinder was used to prepare the HPO after evacuation by a turbomolecular pump.
2 The source gases were filled in the order of the mixtures of CO_2 in Ar, pure O_2 and pure N_2 in a filling room where the
3 temperature was controlled at 23 ± 1 °C and humidity was not regulated. The mass of the CO_2 in Ar standard mixture filled
4 was determined by the difference in the mass of the cylinder before and after filling with the mixture. The masses of the filled
5 pure O_2 and N_2 were treated in the same manner. The final pressure in the cylinder was 12 MPa, and masses of the individual
6 gases were approximately 18 g of CO_2 in Ar standard mixture, 300 g of pure O_2 , and 1000 g of pure N_2 .

7 **2.2 Weighing procedure for a cylinder**

8 The masses obtained for the cylinders were determined using the same weighing system as reported by Matsumoto et al.
9 (2004), except for the mass comparator. The mass comparator used in the study of Matsumoto et al. was replaced with a new
10 mass comparator (XP26003L, Mettler Toledo, Switzerland), which had a maximum capacity of 26.1 kg, a sensitivity of 1 mg,
11 and a linearity of 20 mg. In this study, a cylinder whose mass was measured is hereafter referred to as a “sample cylinder”.
12 Mass measurement for sample cylinders was performed in a weighing room where temperature and humidity were controlled
13 at 26 ± 0.5 °C and 48 ± 1 %, respectively. The temperature, humidity, and atmospheric pressure surrounding our weighing
14 system were measured using a USB connectable logger (TR-73, T and D Corporation, Japan).

15 Mass measurements of the sample cylinder were conducted with respect to an almost identical reference cylinder aiming to
16 reduce any influence exerted by zero-point drifts, sensitivity issues associated with the mass comparator, changes in buoyancy
17 acting on the cylinder, and/or adsorption effects on the cylinder surface due to the presence of water vapor (Alink et al., 2000;
18 Milton et al., 2011). This is carried out according to several consecutive weighing operations in the ABBA order sequence,
19 where “A” and “B” denote the reference cylinder and the sample cylinder, respectively. The process of loading and unloading
20 of the cylinders was automated. One complete cycle of the ABBA sequence required five minutes. The “mass reading”
21 recorded by our weighing system was given as the difference between both cylinders mass readings, which was obtained by
22 subtracting the reference cylinder reading from the sample cylinder reading.

23 Because the output of mass comparators is generally known to be nonlinear, there is a tendency to under- or over-estimate
24 mass readings for the sample cylinders in our weighing system. This is because the relation between the output of mass
25 comparators and the mass of artefacts tend to be different among various scale ranges. To reduce the influence of this
26 nonlinearity, sample cylinders were weighed only when the difference in readings between the sample and reference cylinders
27 was less than 500 mg. This was achieved by placing standard weights on a weighing pan alongside the sample or reference
28 cylinder. Any mass differences obtained in our weighing system took into account the masses and buoyancies of the standard
29 weights. The masses of the standard weights were traceable to the International System of Units. The standard uncertainties
30 of the masses were 0.25 mg, 0.045 mg, 0.028 mg, 0.022 mg, 0.018 mg, 0.014 mg, 0.011 mg, and 0.0090 mg for the 500 g,
31 100 g, 50 g, 20 g, 10 g, 5 g, 2 g, and 1 g weights, respectively.

32 Temperatures of the sample and reference cylinders were alternately measured by a thermocouple-type thermometer with a
33 resolution of 0.1 K (TX1001 digital thermometer, probe-90030, Yokogawa Test and Measurement Corporation, Tokyo, Japan)
34 before and after weighing of the cylinders.

2.3 Determination procedure of isotopic abundances for O and N

Each HPO was prepared using pure O₂ from two 48 L cylinders and pure N₂ from three or four 48 L cylinders as source gases. The isotopic abundances (¹⁶O, ¹⁷O, ¹⁸O, ¹⁴N, and ¹⁵N) for pure O₂ and N₂ may be different between cylinders, resulting in abundance differences among each HPO. The averaged values of isotopic abundances in pure O₂ (two cylinders) and pure N₂ (three or four cylinders) used for the respective HPOs were calculated based on the ratios of ¹⁸O/¹⁶O, ¹⁷O/¹⁶O, and ¹⁵N/¹⁴N in the HPOs. These were calculated using the equations, $^{18}\text{O}/^{16}\text{O} = [\delta(^{18}\text{O}/^{16}\text{O}) + 1] \times (^{18}\text{O}/^{16}\text{O})_{\text{ref}}$, $^{17}\text{O}/^{16}\text{O} = [\delta(^{17}\text{O}/^{16}\text{O}) + 1] \times (^{17}\text{O}/^{16}\text{O})_{\text{ref}}$, and $^{15}\text{N}/^{14}\text{N} = [\delta(^{15}\text{N}/^{14}\text{N}) + 1] \times (^{15}\text{N}/^{14}\text{N})_{\text{ref}}$. The terms $\delta(^{17}\text{O}/^{16}\text{O})$, $\delta(^{18}\text{O}/^{16}\text{O})$, and $\delta(^{15}\text{N}/^{14}\text{N})$ which were determined by a mass spectrometer (Delta-V, Thermo Fisher Scientific Inc., USA) represent the deviation from the corresponding atmospheric value (Ishidoya and Murayama, 2014). The isotopic ratios of $\delta(^{17}\text{O}/^{16}\text{O})$, $\delta(^{18}\text{O}/^{16}\text{O})$, and $\delta(^{15}\text{N}/^{14}\text{N})$ were approximately equal to those of $\delta(^{17}\text{O}^{16}\text{O}/^{16}\text{O}^{16}\text{O})$, $\delta(^{18}\text{O}^{16}\text{O}/^{16}\text{O}^{16}\text{O})$, and $\delta(^{15}\text{N}^{14}\text{N}/^{14}\text{N}^{14}\text{N})$, since $^{17}\text{O}^{17}\text{O}/^{16}\text{O}^{16}\text{O}$, $^{18}\text{O}^{18}\text{O}/^{16}\text{O}^{16}\text{O}$ and $^{15}\text{N}^{15}\text{N}/^{14}\text{N}^{14}\text{N}$ tended to be much less than $^{17}\text{O}^{16}\text{O}/^{16}\text{O}^{16}\text{O}$, $^{18}\text{O}^{16}\text{O}/^{16}\text{O}^{16}\text{O}$ and $^{15}\text{N}^{14}\text{N}/^{14}\text{N}^{14}\text{N}$. Values of $(^{18}\text{O}/^{16}\text{O})_{\text{ref}}$, $(^{17}\text{O}/^{16}\text{O})_{\text{ref}}$, and $(^{15}\text{N}/^{14}\text{N})_{\text{ref}}$ refer to ratios of ¹⁸O/¹⁶O, ¹⁷O/¹⁶O, and ¹⁵N/¹⁴N in reference air. In the present study, natural air in a 48 L aluminium cylinder (Cylinder No. CRC00045), equipped with a diaphragm valve (G-55, Hamai Industries Limited, Japan) was used as reference air in the AIST scale (hereafter referred to AIST reference air). The AIST reference air was prepared in 2011 by filling natural air into the cylinder to a pressure of about 13 MPa after drying cryogenically by using a highly efficient water trap at the dew point temperature lower than -80 °C (Ishidoya and Murayama, 2014). It has been confirmed that the $\delta(\text{O}_2/\text{N}_2)$ on the AIST scale is higher by several hundred per meg than that on the Scripps Institution of Oceanography (SIO) scale (e.g. Manning and Keeling, 2006) by reflecting the difference of the filling years of the respective references for AIST and SIO scales (Ishidoya et al., 2016). The corresponding atmospheric values shown in Table 1 were used as the ratios of $(^{17}\text{O}/^{16}\text{O})_{\text{ref}}$, $(^{18}\text{O}/^{16}\text{O})_{\text{ref}}$, and $(^{15}\text{N}/^{14}\text{N})_{\text{ref}}$, as isotopic abundances in the troposphere are considered to be constant (Junk and Svec, 1958; Baertschi, 1976; Li et al., 1988; Barkan and Luz, 2005). Because differences between isotopic ratios of N₂, O₂, Ar in the AIST reference air and air samples at Hateruma were sufficiently small to be negligible, their fractionations due to preparation of the AIST reference air are ignored.

2.4 Analytical methods

In this study, a mass spectrometer was used to determine O₂/N₂ and Ar/N₂ ratios in the HPOs. A cavity ring-down spectrometer was used to examine consistency among molar fractions of CO₂ in the HPOs. In this section, we describe the analytical methods and relationships between the absolute O₂/N₂ (Ar/N₂) ratios and the mass-spectrometry based isotopic ratios.

2.4.1 Evaluations of O₂/N₂ and Ar/N₂ ratios in highly precise O₂ standard mixtures and natural air

Ratios of O₂/N₂ and Ar/N₂ in the HPOs were validated by comparison of gravimetrically calculated values with the measured values obtained by the mass spectrometer (Delta-V, Thermo Fisher Scientific Inc., USA). The mass spectrometer was adjusted to measure ion beam currents for masses 28 (¹⁴N¹⁴N), 29 (¹⁵N¹⁴N), 32 (¹⁶O¹⁶O), 33 (¹⁷O¹⁶O), 34 (¹⁸O¹⁶O), 36 (³⁶Ar), 40 (⁴⁰Ar), and 44 (¹²C¹⁶O¹⁶O) simultaneously. Isotopic ratios of $\delta(^{15}\text{N}^{14}\text{N}/^{14}\text{N}^{14}\text{N})$, $\delta(^{17}\text{O}^{16}\text{O}/^{16}\text{O}^{16}\text{O})$, $\delta(^{18}\text{O}^{16}\text{O}/^{16}\text{O}^{16}\text{O})$, $\delta(^{16}\text{O}^{16}\text{O}/^{14}\text{N}^{14}\text{N})$, $\delta(^{36}\text{Ar}/^{40}\text{Ar})$, and $\delta(^{40}\text{Ar}/^{14}\text{N}^{14}\text{N})$ were determined against the AIST reference air using the mass spectrometer. In our prepared HPOs, the ratios of $\delta(\text{O}_2/\text{N}_2)_{\text{HPO_grav}}$ and $\delta(\text{Ar}/\text{N}_2)_{\text{HPO_grav}}$, comprised of all isotopes of O₂, N₂ and Ar and gravimetrically calculated, are not equal to the isotopic ratios of $\delta(^{16}\text{O}^{16}\text{O}/^{14}\text{N}^{14}\text{N})_{\text{HPO_meas}}$ and

1 $\delta(^{40}\text{Ar}/^{14}\text{N}^{14}\text{N})_{\text{HPO_meas}}$ measured by the mass spectrometer. This is because the isotopic ratios in source gases are different
 2 from the corresponding atmospheric values. The subscripts “HPO_grav” and “HPO_meas” hereafter refer to the gravimetric
 3 value and the measured value in the HPO. Thus, mass-spectrometry based isotopic ratios need to be converted to values
 4 equivalent to the $\delta(\text{O}_2/\text{N}_2)_{\text{HPO_grav}}$ ratio and the $\delta(\text{Ar}/\text{N}_2)_{\text{HPO_grav}}$ ratio. The values of $\delta(\text{O}_2/\text{N}_2)_{\text{HPO_meas}}$ and $\delta(\text{Ar}/\text{N}_2)_{\text{HPO_meas}}$ were
 5 calculated using mass-spectrometry based on isotopic ratios $^{15}\text{N}^{14}\text{N}/^{14}\text{N}^{14}\text{N}$, $^{17}\text{O}^{16}\text{O}/^{16}\text{O}^{16}\text{O}$, $^{18}\text{O}^{16}\text{O}/^{16}\text{O}^{16}\text{O}$, $^{36}\text{Ar}/^{40}\text{Ar}$, and
 6 $^{38}\text{Ar}/^{40}\text{Ar}$ as depicted in equations (3) and (4). Isotopic species of $^{17}\text{O}^{17}\text{O}$, $^{18}\text{O}^{17}\text{O}$, $^{18}\text{O}^{18}\text{O}$, $^{15}\text{N}^{15}\text{N}$, were negligible because the
 7 abundance of these species was very small.

$$9 \quad \delta(\text{O}_2/\text{N}_2)_{\text{HPO_meas}} = [\delta(^{16}\text{O}^{16}\text{O}/^{14}\text{N}^{14}\text{N})_{\text{HPO_meas}} + 1] \times$$

$$10 \quad \left[\frac{1 + ^{17}\text{O}^{16}\text{O}/^{16}\text{O}^{16}\text{O} + ^{18}\text{O}^{16}\text{O}/^{16}\text{O}^{16}\text{O}}{1 + ^{15}\text{N}^{14}\text{N}/^{14}\text{N}^{14}\text{N}} \right]_{\text{HPO}} / \left[\frac{1 + ^{17}\text{O}^{16}\text{O}/^{16}\text{O}^{16}\text{O} + ^{18}\text{O}^{16}\text{O}/^{16}\text{O}^{16}\text{O}}{1 + ^{15}\text{N}^{14}\text{N}/^{14}\text{N}^{14}\text{N}} \right]_{\text{ref}} - 1 \quad (3)$$

$$12 \quad \delta(\text{Ar}/\text{N}_2)_{\text{HPO_meas}} = [\delta(^{40}\text{Ar}/^{14}\text{N}^{14}\text{N})_{\text{HPO_meas}} + 1] \times \left[\frac{1 + ^{36}\text{Ar}/^{40}\text{Ar} + ^{38}\text{Ar}/^{40}\text{Ar}}{1 + ^{15}\text{N}^{14}\text{N}/^{14}\text{N}^{14}\text{N}} \right]_{\text{HPO}} / \left[\frac{1 + ^{36}\text{Ar}/^{40}\text{Ar} + ^{38}\text{Ar}/^{40}\text{Ar}}{1 + ^{15}\text{N}^{14}\text{N}/^{14}\text{N}^{14}\text{N}} \right]_{\text{ref}} - 1$$

$$13 \quad (4)$$

15 The values of $^{15}\text{N}^{14}\text{N}/^{14}\text{N}^{14}\text{N}$, $^{17}\text{O}^{16}\text{O}/^{16}\text{O}^{16}\text{O}$, and $^{18}\text{O}^{16}\text{O}/^{16}\text{O}^{16}\text{O}$ in the HPOs and the AIST reference air were calculated using
 16 isotope abundances of O and N determined by the procedure described in section 2.3 (Table 1). The $^{36}\text{Ar}/^{40}\text{Ar}$ ratio of pure
 17 Ar filled in the HPOs was calculated using equation $^{36}\text{Ar}/^{40}\text{Ar} = [\delta(^{36}\text{Ar}/^{40}\text{Ar})_{\text{HPO_meas}} + 1] \times (^{36}\text{Ar}/^{40}\text{Ar})_{\text{ref}}$. The
 18 $\delta(^{36}\text{Ar}/^{40}\text{Ar})_{\text{HPO_meas}}$ value was determined by mass spectrometry of the HPOs. The $(^{36}\text{Ar}/^{40}\text{Ar})_{\text{ref}}$ value obtained was the
 19 atmospheric value ($^{36}\text{Ar}/^{40}\text{Ar} = 0.003349 \pm 0.000004$), because isotopic abundances of Ar in the AIST reference air were
 20 equal to that of the atmospheric value. The value of $^{38}\text{Ar}/^{40}\text{Ar}$ in the HPOs and the AIST reference air, which could not be
 21 measured, was assumed to be $^{38}\text{Ar}/^{40}\text{Ar} = 0.000631 \pm 0.000004$ taken from previous reports as the atmospheric values.
 22 Deviations of respective abundances of ^{38}Ar from the atmospheric value were considered to be less than the uncertainty of the
 23 atmospheric value for ^{38}Ar . The atmospheric values of isotopic abundances for Ar were reported in an IUPAC technical report
 24 (Böhlk, 2014).

25 On the other hand, the absolute O_2/N_2 ratio in the AIST reference air was calculated by substituting the $(\text{O}_2/\text{N}_2)_{\text{HPO_grav}}$ in the
 26 HPOs and the $\delta(\text{O}_2/\text{N}_2)_{\text{HPO_meas}}$ for $(\text{O}_2/\text{N}_2)_{\text{sam}}$ and for $\delta(\text{O}_2/\text{N}_2)$ in equation (1). The absolute Ar/ N_2 ratio in the AIST reference
 27 air was calculated in same manner (see the section 5.3).

28 **2.4.2 Measurements of CO₂ in highly precise O₂ standard mixtures**

29 Molar fractions of CO₂ in HPOs were verified using a cavity ring-down spectrometer (G2301, Picarro Inc., USA) equipped
 30 with a multi-port valve (Valco Instruments Co. Inc., USA) for gas introduction and a mass flow controller (SEC-N112,
 31 100SCCM, Horiba STEC, CO., Ltd, Japan). The cavity ring-down spectrometer was calibrated by three primary standard
 32 gases ($364.50 \pm 0.14 \mu\text{mol mol}^{-1}$, $494.04 \pm 0.14 \mu\text{mol mol}^{-1}$, and $500.32 \pm 0.14 \mu\text{mol mol}^{-1}$) that had been prepared from pure
 33 CO₂ and purified Air (G1 grade, Japan Fine Products, Japan) in accordance with ISO 6142-1:2015. The individual standard
 34 gases were continuously measured for 30 minutes, respectively and the data last ten minutes were used. The pure CO₂ was
 35 the same as the source gas used for preparation of the HPOs.

1 **3 Identifying and minimizing unknown factors of uncertainty**

2 As previously mentioned,, there are several unknown factors that influence mass readings obtained for sample cylinders.
3 Identifying and minimizing these unknown factors is discussed in this section.

4 **3.1 Factors to cause deviations of mass readings**

5 Generally, mass readings of a sample cylinder obtained from a mass comparator tend to vary due to numerous factors such as
6 buoyancy, adsorption/desorption and thermal effects. The buoyancy effect is caused by changes in the density of the
7 surrounding air due to variations in ambient temperature, humidity, and pressure. Adsorption effect can greatly influence mass
8 readings of a sample cylinder by adsorption and desorption of water vapor from surrounding ambient air on the external
9 surface of a sample cylinder (Alink et al., 2000; Mizushima, 2004, 2007; Milton et al., 2011). The thermal effect is related to
10 temperature gradients between a sample cylinder and the surrounding ambient air (Gläser, 1990, 1999; Mana et al., 2002;
11 Gläser and Borys, 2009; Schreiber et al., 2015), which is able to change the weight force of the sample cylinder through
12 frictional forces exerted on the vertical surface of a sample cylinder and pressure forces on the horizontal surface. Both the
13 friction and pressure forces are caused by the upward or downward flow of air that is heated or cooled, respectively, by the
14 sample cylinder.

15 When the ABBA technique is employed for mass measurements under identical experimental conditions, the deviations of
16 the mass readings due to the factors described above become negligible because they are equally exerted on both the sample
17 and the reference cylinder. In fact, the buoyancy effect could be cancelled by adopting the ABBA technique in our mass
18 measurements (see Section 4.3.1). On the other hand, the identical experimental conditions tend to be disturbed by the
19 temperature change on the sample cylinder surface by adiabatic compression of the source gases and by the temperature
20 difference between the filling room and the weighing room. Mass readings of the sample cylinder deviate from true values
21 when thermal effects due to a change in the sample cylinder surface temperature are exerted independently and at varying
22 degrees on the sample and reference cylinders. Moreover, the amount of water adsorbed on the sample cylinder surface can
23 also be influenced by humidity if the level in the filling room is different from that in the weighing room. This non-uniformity
24 of temperatures and the water amount between the sample cylinder surface and the surrounding ambient air is assumed to be
25 the main contributor of uncertainties in obtained mass readings of the sample cylinder (Matsumoto et al., 2008). In order to
26 identify and minimize the contribution to the non-uniformity, we examined the equilibrium of both humidity and temperature
27 for the surface of the sample cylinder used in this study before carrying out any measurement.

28 **3.2 Identifying and minimizing unknown uncertainty factors**

29 Equilibrium in the temperature and the water amount between the sample cylinder surface and its surrounding ambient air is
30 considered to be achieved by placing the sample cylinder on our weighing system for an appropriate duration of time before
31 the mass reading. Here, the equilibrium between the reference cylinder surface and its surrounding ambient air is always
32 achieved as the reference cylinder is permanently left on the weighing system. The equilibrium for the sample cylinder is
33 easily disturbed by the processes of its evacuation and filling of the source gases. To quantify the appropriate time interval
34 needed to restore equilibrium, the mass readings of the sample cylinder were recorded after the evacuation and after the filling.
35 These values were plotted against the time elapsed after evacuation and filling (Figure 1). The surface temperature of the

1 sample cylinder recorded after the evacuation was 2 K lower, while the temperatures recorded after the filling for CO₂ in Ar
2 standard mixture, pure O₂, and pure N₂ were -0.7 K, 1 K, and 6 K higher than that of the reference cylinder, respectively. In
3 this experiment, the equilibria were considered to be achieved when the standard deviation of the mass readings remained
4 constant for two or more hours with the repeatability value of < 0.82 mg (see in Section 4.3.1.). Interestingly, the mass readings
5 recorded after the evacuation and filling for CO₂ in Ar mixture tended to decrease as time elapsed, while those after filling
6 with pure O₂ and N₂ gases tended to increase. Deviations in mass readings had some connection with the temperature
7 difference between the reference and sample cylinders. The results imply that warmer cylinders appear lighter.

8 Appropriate time intervals were defined as the time elapsed from the evacuation or the filling time to the point of re-achieving
9 equilibrium. This time interval was noted as 5 h after complete evacuation. Time intervals required after filling with relevant
10 gases were different depending on the filled gas species to some extent. For the CO₂ in Ar mixture, equilibria were achieved
11 in 3 h to 5 h, while 4 h to 5 h were required for O₂ equilibration and 7 h to 9 h for N₂. These intervals indicate that preparation
12 of a single HPO requires several days. To determine the mass of the sample cylinder in as short time as possible, a clear
13 indicator for carrying out mass measurement is needed.

14 As described above, the deviations in mass readings are considered to have some relation with the temperature differences in
15 the sample and reference cylinders. Therefore, we proceeded to examine this relationship to understand whether the
16 temperature difference can be the indicator. The closed squares shown in Figure 2 indicate that the deviation of mass readings
17 was proportional to temperature differences. This deviation rate was determined to be -14.3 mg K⁻¹. Although the results
18 indicate that a temperature difference of 0.1 K causes a deviation of 1.4 mg, the deviation in the recorded mass readings
19 ensures the repeatability value of 0.82 mg that is achieved by reducing the temperature difference to below 0.06 K. By
20 conducting measurements of the cylinder temperature using the thermocouple-type thermometer and ensuring that the mass
21 readings were taken when the temperature of both cylinders were the same, we were able to reduce the deviation contributing
22 to the mass readings.

23 To validate the proposed weighing procedure, the reproducibility of mass readings obtained after disturbing the equilibrium
24 was measured. Hence, the mass reading sequence after a cooling or heating cycle of the cylinders was examined. Figure 3
25 illustrates the results in which four heating cycles (number 1 to 4) and four cooling cycles (number 5 to 8) were conducted.
26 In this experiment, temperatures of the cooled or heated cylinder were 1 K to 3 K lower or 10 K to 20 K higher than that of
27 the reference cylinder, respectively. When mass readings were recorded after ensuring equal temperatures of both the sample
28 and reference cylinders, no difference in mass readings recorded after the cooling and heating cycles was detected. The
29 reproducibility of mass readings was estimated to be 0.44 mg with regards to the standard deviation of the mass readings
30 shown in Figure 3. The fact that reproducibility was lower than the repeatability value validated the weighing procedure. The
31 contributions to mass readings by non-equilibrium conditions were negligible using the established weighing procedure.

32 It is difficult to determine whether deviations in mass readings recorded for sample cylinders were caused by thermal or
33 adsorption effects simply by analysing these results. This is because both effects are related to temperature fluctuations.
34 However, the thermal effect influenced the slope of the calibration function solely through temperature differences, whereas
35 the adsorption/desorption effect influenced the slope of the calibration function via a combination of both ambient temperature
36 and humidity. This is because the adsorbed or desorbed amounts of water on the surface of both cylinders are highly dependent
37 on the cylinder temperature and humidity of the surrounding ambient air. To determine which of these effects contributed the

1 most to the deviations, the relationship between the deviations and temperature differences was investigated under various
 2 conditions in the weighing room. Humidity was stringently controlled at 30%, 50%, 65%, and 80%, whereas temperature
 3 levels were maintained at 22 °C, 26 °C, and 29 °C. As shown in Figure 2, the slope did not depend on the humidity nor
 4 temperature. These results indicate that the dominant factor of deviations in mass readings was rather an effect of thermal
 5 gradients than adsorption, because the deviations depended on the temperature difference only. Therefore, we focused on
 6 minimizing the impact of any thermal gradient in further experiments.

7 **4 Evaluation of uncertainty factors for the O₂ Standard Mixtures**

8 In this section, we discuss any uncertainty factors associated with molar fractions of constituents in the HPOs. The gravimetric
 9 molar fraction (y_k) of the constituent k (CO₂, Ar, O₂, and N₂) was calculated using the molar mass (M_i) and the molar fraction
 10 ($x_{i,j}$) of the constituent i (CO₂, Ar, O₂, N₂ and impurities) in the filled source gas j (CO₂ in Ar standard mixture, pure O₂, and
 11 pure N₂). Additionally, mass (m_j) of the source gases filled into the sample cylinder were incorporated into equation (5) in
 12 accordance with ISO 6142-1:2015.

13

$$14 \quad y_k = \frac{\sum_{j=1}^r \left(\frac{x_{k,j} \times m_j}{\sum_{i=1}^q x_{i,j} \times M_i} \right)}{\sum_{j=1}^r \left(\frac{m_j}{\sum_{i=1}^q x_{i,j} \times M_i} \right)} \quad (5)$$

15

16 In this equation, r and q represent the number of source gases j and constituents i , respectively, while $x_{k,j}$ is the molar fraction
 17 of the constituent k in the source gas j . Uncertainties ($u(y_k)$) associated with the gravimetric molar fraction were calculated
 18 according to the law of propagation.

19

$$20 \quad u^2(y_k) = \sum_{j=1}^r \sum_{i=1}^q \left(\frac{\partial y_k}{\partial x_{i,j}} \right)^2 \times u^2(x_{i,j}) + \sum_{i=1}^q \left(\frac{\partial y_k}{\partial M_i} \right)^2 \times u^2(M_i) + \sum_{j=1}^r \left(\frac{\partial y_k}{\partial m_j} \right)^2 \times u^2(m_j) \quad (6)$$

21

22 In this equation, $u(A)$ depicts the standard uncertainty for A . Gravimetric molar fractions of the constituent k and its associated
 23 uncertainty in the molar fractions for the HPOs prepared in this study were calculated using equation (5) and equation (6),
 24 and they are listed in Table 2. The standard uncertainties for the constituents N₂, O₂, Ar, and CO₂ were 0.8 – 1.0 μmol mol⁻¹,
 25 0.7 – 0.8 μmol mol⁻¹, 0.6 – 0.7 μmol mol⁻¹, and 0.03 μmol mol⁻¹, respectively. Table 3 lists the contribution of the purity of
 26 the source gases, molar masses of the constituents, and masses of the source gases to the gravimetric molar fraction. These
 27 correspond to the square root of the first, second, and third terms found in equation (6), respectively. Uncertainty factors in
 28 the gravimetric molar fractions in the HPOs were mainly those of the mass for the source gases filled into the sample cylinder.
 29 Contributions from other sources of uncertainty were negligible. Purity of the source gases and molar masses of the
 30 constituents i , as well as the masses of the source gases and their associated standard uncertainties, are described in Sections
 31 4.1, 4.2, and 4.3.

1 **4.1 Purity of source gas**

2 Pure O₂, N₂, Ar, and CO₂ were used as source gases to prepare the HPOs. Molar fractions of impurities presented in source
3 gases and their associated standard uncertainties were determined based on the primary standard gases prepared in accordance
4 with ISO 6142-1:2015. When the molar fraction of impurity h was under its detection limit (L_h), the molar fraction (x_h) and
5 standard uncertainty ($u(x_{h,j})$) of h in the source gas j was calculated using the equations $x_{h,j} = L_{h,j}/2$ and $(x_{h,j}) =$
6 $L_{h,j}/2\sqrt{3}$. The calculated values for the impurities and purities of the source gases are listed in Table 4.

7 **4.2 Molar masses of constituents**

8 Molar masses (M_i) of the constituents were calculated using most recent atomic masses and isotopic abundances reported by
9 the IUPAC. However, IUPAC values for atomic masses of O and N have large standard uncertainties because they reflect
10 variability present in individual isotopic abundances of natural terrestrial matter. Using IUPAC values, standard uncertainties
11 for N₂ and O₂ molar fractions in the HPOs were calculated to be 4 $\mu\text{mol mol}^{-1}$. In addition, atmospheric values of their isotopic
12 abundances could not be used for calculating molar masses of the source gases even though pure O₂ and N₂ were produced
13 from air. This is because isotopically abundant O and N in pure O₂ and N₂ tends to deviate from the corresponding atmospheric
14 value during the production process. Therefore, the isotopic abundances of O and N in HPOs were precisely determined using
15 mass spectrometry. Their isotopic abundance and associated standards of uncertainty are shown in Table 1. The difference of
16 isotopic abundances of O and N between respective HPOs were negligible.

17 Based on the isotopic abundances obtained in this study and the atomic masses of O and N in the filled source gases, pure O₂
18 and N₂ were determined with relative standard uncertainties of 0.000029 % and 0.000006 %, respectively. It was shown that
19 the uncertainty in molar masses is negligible (Table 3). Although the grade and supplier of the pure O₂ and N₂ used in this
20 study were the same as those of the source gases used by Tohjima et al. (2005), the atomic masses (15.999366 (1) for O and
21 14.006717 (4) for N) obtained for the two elements were different from Tohjima et al. reported values (15.999481 (8) for O
22 and 14.006677 (4) for N). These differences resulted in a deviation of 0.4 $\mu\text{mol mol}^{-1}$ and 1.2 $\mu\text{mol mol}^{-1}$ for O₂ and N₂,
23 respectively. Since these results infer that the ratios of O and N isotopes change with production time, the isotopic abundances
24 of O and N in the source gases have to be precisely determined whenever HPOs are prepared using different pure O₂ and N₂.
25 On the other hand, standard uncertainties in the atomic mass presented in an IUPAC technical report by De Laeter et al. (2003)
26 were sufficient for further use in the case of Ar and CO₂ as source gases.

27 **4.3 Determining the masses of the filled gases**

28 Masses of individual gases that were filled into the sample cylinders were calculated using the mass difference before and
29 after the filling. The standard uncertainty of the obtained mass was calculated by combining standard uncertainties of mass
30 readings of the sample cylinder before and after filling each gas. To determine uncertainty in mass reading of the sample
31 cylinder, three factors were evaluated i.e., the repeatability $u(m_{rep})$ of the mass readings, permeation $u(m_{gas\ permeate})$ of
32 the source gases during weighing, and buoyancy change $u(m_{buoyancy})$ due to the expansion of the cylinder. The standard
33 uncertainties ($u(m_{cyl})$) were defined according to equation (7).

34

1 $u^2(m_{cyl}) = u^2(m_{rep}) + u^2(m_{gas\ permeate}) + u^2(m_{buoyancy}).$ (7)

2

3 These factors are discussed in detail in sections 4.3.1, 4.3.2, and 4.3.3. The standard uncertainties of masses for the individual
4 filled gases were 1.2 mg regardless of the gas species.

5 **4.3.1 Repeatability of mass readings**

6 The repeatability of mass readings was evaluated by continuous mass measurement of sample cylinders using the ABBA
7 technique over three days. This is because preparation of a single HPO requires three days. Mass readings were recorded after
8 the sample cylinder was left on the weighing system for at least a week. Air density was likewise measured for three days by
9 carefully monitoring temperature, humidity, and pressure changes in ambient air (Figure 4). Our findings indicate that the
10 mass readings remain stable during the three-day experiment. The standard deviation of mass readings (0.82 mg) is
11 represented as repeatability $u(m_{rep})$. The fact that the mass readings were not affected by changes in the air density also
12 indicates that buoyancy issues influencing the sample cylinder were cancelled out by changes simultaneously affecting the
13 reference cylinder.

14 **4.3.2 Permeation of source gases during weighing**

15 All of the cylinders used in this study have diaphragm valves, which were joined to the cylinders via pipe fittings and sealed
16 with Teflon tape. The seal of diaphragm valves was made from PCTFE, through which gases tend to permeate quite slowly
17 (Sturm, 2004). Since permeation of the source gases during weighing the sample cylinders resulted in evaluation error of the
18 masses for the source gases, we examined the permeability of purified air by monitoring mass of the sample cylinder filled
19 with purified air at a pressure of 8 MPa. The changes in mass readings were measured for over four months. From these results,
20 it was determined that the permeability was 0.013 mg day^{-1} . This effect was considered to be negligible because it is much
21 lower than the repeatability. Therefore, the contribution of permeability ($u(m_{gas\ permeate})$) to the standard uncertainty
22 calculations ($u(m_{cyl})$) was ignored. On the other hand, the amount of air permeating from the sample cylinder during the
23 course of a year was calculated to be about 4.7 mg. This quantity may cause changes in the composition of the HPO if the
24 mixture is kept for extended periods of time, since the gas permeability depends on the gas species (Sturm, 2004).

25 **4.3.3 Buoyancy effect of cylinder expansion**

26 Oh et al. (2013) reported that volume in the 10 L aluminium cylinders linearly increases with increase in internal pressure,
27 and volume expansion was determined to be $24 \pm 2\text{ ml}$ when the pressure difference in the sample cylinders was 12 MPa.
28 Tohjima et al. (2005) likewise reported a volume expansion of $22 \pm 4\text{ ml}$ when the pressure difference was 10 MPa. In this
29 study, we adopted a volume expansion of the sample cylinders as $55 \pm 5\text{ ml}$, measured by a cylinder supplier, when the
30 pressure difference was 25 MPa. Compared to the expansion rate with respect to pressure variations reported by Oh (2.0 ± 0.2
31 ml MPa^{-1}) (2013) and Tohjima ($2.2 \pm 0.4\text{ ml MPa}^{-1}$) (2005), expansion rate of the sample cylinders used in this study was
32 determined to be $2.2 \pm 0.2\text{ ml MPa}^{-1}$. The pressure difference recorded before and after filling with source gases was 0.12
33 MPa, 2.5 MPa, and 9.4 MPa for CO₂ in Ar standard mixture, pure O₂, and pure N₂, respectively. These pressure differences
34 were subsequently used to calculate buoyancy effects, which were reported as 0.3 mg, 6.4 mg, and 23.9 mg for CO₂ in Ar

1 standard mixture, pure O₂, and pure N₂, respectively. In turn, these buoyancy effects caused changes in the gravimetric molar
2 fraction of +0.5 μmol mol⁻¹ and -0.5 μmol mol⁻¹ for O₂ and N₂, respectively. The final mass readings were corrected to take
3 these changes into account. The standard uncertainties $u(m_{buoyancy})$ in linear expansion were considered to be negligible.

4 **5 Validation of the constituents in the highly precise O₂ standard mixtures**

5 The O₂ molar fractions in the HPOs deviate from gravimetric values with deviation of the molar fractions of other constituents.
6 In this section, the molar fractions of all constituents were validated. The gravimetric and measured values for the CO₂ molar
7 fractions were compared, along with the values of $\delta(\text{Ar}/\text{N}_2)_{\text{HPO_grav}}$, $\delta(\text{Ar}/\text{N}_2)_{\text{HPO_meas}}$, $\delta(\text{O}_2/\text{N}_2)_{\text{HPO_grav}}$ and $\delta(\text{O}_2/\text{N}_2)_{\text{HPO_meas}}$ to
8 validate the molar fractions of Ar, O₂ and N₂ in the HPOs. Table 5 shows the $\delta(\text{O}_2/\text{N}_2)_{\text{HPO_meas}}$ and $\delta(\text{Ar}/\text{N}_2)_{\text{HPO_meas}}$ values
9 calculated using equation (3) and (4), as well as the values for $\delta(^{15}\text{N}^{14}\text{N}/^{14}\text{N}^{14}\text{N})_{\text{HPO_meas}}$, $\delta(^{17}\text{O}^{16}\text{O}/^{16}\text{O}^{16}\text{O})_{\text{HPO_meas}}$,
10 $\delta(^{18}\text{O}^{16}\text{O}/^{16}\text{O}^{16}\text{O})_{\text{HPO_meas}}$, $\delta(^{16}\text{O}^{16}\text{O}/^{14}\text{N}^{14}\text{N})_{\text{HPO_meas}}$, $\delta(^{36}\text{Ar}/^{40}\text{Ar})_{\text{HPO_meas}}$, and $\delta(^{38}\text{Ar}/^{40}\text{Ar})_{\text{HPO_meas}}$.

11 **5.1 Determining the absolute (O₂/N₂) and (Ar/N₂) ratios in AIST reference air**

12 The absolute $(\text{O}_2/\text{N}_2)_{\text{HPO_grav}}$ and $(\text{Ar}/\text{N}_2)_{\text{HPO_grav}}$ ratios, as well as the $\delta(\text{O}_2/\text{N}_2)_{\text{HPO_meas}}$ and $\delta(\text{Ar}/\text{N}_2)_{\text{HPO_meas}}$ values of the HPOs
13 are listed in Table 2 and Table 5. Using these values, the absolute ratios for O₂/N₂ and Ar/N₂ in AIST reference air were
14 0.2680929 ± 0.0000016 and 0.0119542 ± 0.0000009 , respectively. On the AIST scale, these values corresponded to $\delta(\text{O}_2/\text{N}_2)$
15 $= 0$ and $\delta(\text{Ar}/\text{N}_2) = 0$. Associated standard uncertainties were determined with regards to the law of propagation of uncertainty.
16 The HPOs prepared in this study did not include minor components of Ne, He, Kr, CH₄, H₂ and N₂O which are present in air
17 samples. Therefore, the variation of the $\delta(^{15}\text{N}^{14}\text{N}/^{14}\text{N}^{14}\text{N})$, $\delta(^{17}\text{O}^{16}\text{O}/^{16}\text{O}^{16}\text{O})$, $\delta(^{18}\text{O}^{16}\text{O}/^{16}\text{O}^{16}\text{O})$, $\delta(^{16}\text{O}^{16}\text{O}/^{14}\text{N}^{14}\text{N})$, $\delta(^{36}\text{Ar}/^{40}\text{Ar})$,
18 and $\delta(^{40}\text{Ar}/^{14}\text{N}^{14}\text{N})$ values obtained by the measurement of mass spectrometry was examined when molar fractions of Ne
19 change from 0 μmol mol⁻¹ to 500 μmol mol⁻¹. Consequently, the isotopic ratios did not change significantly depending on
20 Ne. Since abundance of Ne is highest in minor components, the changes of the molar fractions of other minor components
21 also might fail to affect the isotopic ratios measured in this study.

22 **5.2 CO₂ molar fractions and Ar/N₂ ratio**

23 Three primary standard gases were used to measure CO₂ molar fractions in HPOs. Table 2 illustrates the gravimetric and
24 measured values and associated standard uncertainties. The CO₂ molar fractions in the cylinder labelled CPB28679, which
25 had been prepared on 29 March 2017, were not measured. Differences between the gravimetric and measured values (obtained
26 by subtracting the measured value from gravimetric value) were found to range from -0.17 μmol mol⁻¹ to 0.03 μmol mol⁻¹.
27 The gravimetric values were in line with the measured values, both being within the accepted levels of uncertainty.
28 From these results, mass of the CO₂ in Ar standard mixture which we evaluated were considered validated. Figure 5 shows
29 the plot of the $\delta(\text{Ar}/\text{N}_2)_{\text{HPO_meas}}$ values relative to the $\delta(\text{Ar}/\text{N}_2)_{\text{HPO_grav}}$ values, as well as the residuals of the $\delta(\text{Ar}/\text{N}_2)_{\text{HPO_meas}}$
30 values that had been estimated using the best fitted line by the least squares method. The standard deviation of the residuals
31 was 78 per meg. This standard deviation represents a scatter in the $(\text{Ar}/\text{N}_2)_{\text{HPO_grav}}$ values, since the standard uncertainty for
32 $\delta(\text{Ar}/\text{N}_2)_{\text{HPO_meas}}$ was much smaller than the obtained standard deviation (Ishidoya and Murayama, 2014). The standard
33 uncertainties for $\delta(\text{Ar}/\text{N}_2)_{\text{HPO_grav}}$ values ranged from 65 per meg to 77 per meg. Standard uncertainties were comparable to

1 the standard deviations obtained for the residuals, supporting the validity of uncertainty calculations for the constituents, Ar
2 and N₂.

3 **5.3 O₂/N₂ ratio**

4 Figure 5 shows a plot of the $\delta(\text{O}_2/\text{N}_2)_{\text{HPO_meas}}$ values listed in Table 5 against the $\delta(\text{O}_2/\text{N}_2)_{\text{HPO_grav}}$ values listed in Table 2, as
5 well as residuals from the fitted line by the least squares method. The slope of the fitted line was determined to be $1.00162 \pm$
6 0.00029 , which indicated that the discrepancy between change rates of the $\delta(\text{O}_2/\text{N}_2)_{\text{HPO_meas}}$ values and the $\delta(\text{O}_2/\text{N}_2)_{\text{HPO_grav}}$
7 values was within 0.16%. The standard deviation of the residuals was 3.6 per meg, which proved to be in line with the standard
8 uncertainties for the corresponding gravimetric values since the standard uncertainties for the values of $\delta(\text{O}_2/\text{N}_2)_{\text{HPO_grav}}$ ranged
9 from 3.2 per meg to 4.0 per meg. The agreement with the gravimetric and measured values reinforced the idea that the method
10 for calculating the uncertainties of the constituents, O₂ and N₂, was proper and accurate. On the other hand, the $\delta(\text{O}_2/\text{N}_2)_{\text{HPO_meas}}$
11 values were lower than their $\delta(^{16}\text{O}^{16}\text{O}/^{14}\text{N}^{14}\text{N})_{\text{HPO_meas}}$ counterparts by 18.2 per meg to 27.1 per meg (Table 5) and differences
12 were larger than the standard uncertainties obtained for both values. This means that the $\delta(\text{O}_2/\text{N}_2)$ values in the HPOs should
13 be expressed by $\delta(\text{O}_2/\text{N}_2)_{\text{HPO_meas}}$ rather than $\delta(^{16}\text{O}^{16}\text{O}/^{14}\text{N}^{14}\text{N})_{\text{HPO_meas}}$.

14 The O₂/N₂ ratio of gases delivered from the cylinders may differ from the gravimetric O₂/N₂ ratio by either homogeneous or
15 inhomogeneous fractionation (Leuenberger et al., 2015 Langenfelds et al., 2005 Keeling et al., 2004). In this study, we used
16 the same type of valves and cylinders as in the study of Tohjima et al. (2005). Tohjima et al. examined changes in the O₂/N₂
17 ratio of the HPOs by releasing the inner air into a room at a flow rate of 8 mL min⁻¹ and found that the fractionation of O₂ and
18 N₂ during air release was negligible. Therefore, we chose not to evaluate fractionation in this study.

19 **6 Comparison with Previous Values**

20 To confirm the consistency of the results obtained using the HPOs, we preliminarily compared O₂/N₂ ratios on both the AIST
21 and NIES scale using annual average of $\delta(\text{O}_2/\text{N}_2)$ values in the air sample from Hateruma Island collected from January to
22 December in 2015. Additionally, the molar fraction of atmospheric O₂ and Ar were determined based on the HPOs and then
23 compared with previously reported values to confirm consistency of the results.

24 **6.1 Comparison between O₂/N₂ ratios on the AIST and NIES scales**

25 We observed the atmospheric $\delta(\text{O}_2/\text{N}_2)$ by analysing air samples collected at Hateruma Island from January to December in
26 2015. For the air samples, we confirmed that the isotopic ratios of N₂ and O₂ did not differ significantly from the atmospheric
27 values, such that we regard the $\delta(^{16}\text{O}^{16}\text{O}/^{14}\text{N}^{14}\text{N})$ value measured by the mass spectrometer is equivalent to $\delta(\text{O}_2/\text{N}_2)$ in
28 equation (1). Twice a month, the air samples were collected in two Pyrex glasses arranged in series (one for AIST and the
29 other for NIES). Using these air samples, we determined that the annual average of $\delta(\text{O}_2/\text{N}_2)$ in 2015 on the AIST scale was
30 -63 ± 3 per meg. The number following the symbol \pm denotes the standard uncertainty of the measurement. Using equation
31 (1), the $\delta(\text{O}_2/\text{N}_2)$ value on the AIST scale was then converted to the absolute O₂/N₂ ratio by utilizing the absolute ratio of
32 O₂/N₂ in AIST reference air determined in section 5.1. In 2015, the absolute O₂/N₂ ratio on Hateruma Island was 0.2680761
33 ± 0.0000018 . This value can be converted to the corresponding $\delta(\text{O}_2/\text{N}_2)$ value on the NIES scale using equation (1), since
34 the absolute O₂/N₂ ratio in NIES reference air was reported to be 0.2681708 by Tohjima et al. (2005). The converted $\delta(\text{O}_2/\text{N}_2)$

1 value, which is expressed as $\delta(\text{O}_2/\text{N}_2)_{\text{NIES on AIST}}$ in the following descriptions, was found to be -353 ± 6 per meg on the NIES
2 scale. The uncertainty expresses the 95% confidence interval.

3 On the other hand, the annual average of $\delta(\text{O}_2/\text{N}_2)$ in Hateruma island in 2015 measured by NIES on the NIES scale was -395
4 ± 5 per meg (Tohjima, Y., personal communications). The number following the symbol \pm denotes the standard uncertainty
5 of the measurement (Tohjima et al., 2008). The $\delta(\text{O}_2/\text{N}_2)$ value is expressed as $\delta(\text{O}_2/\text{N}_2)_{\text{NIES on NIES}}$. There was a difference of
6 41 per meg between both values of $\delta(\text{O}_2/\text{N}_2)_{\text{NIES on AIST}}$ and $\delta(\text{O}_2/\text{N}_2)_{\text{NIES on NIES}}$. This difference falls outside of the 95%
7 confidence interval. The disagreement between $\delta(\text{O}_2/\text{N}_2)_{\text{NIES on AIST}}$ and $\delta(\text{O}_2/\text{N}_2)_{\text{NIES on NIES}}$ suggests that there are some
8 inconsistencies between the gravimetric methods developed by Tohjima et al. (2005) and this study. Additionally, other
9 sources of error may exist (e.g. difference between instruments, sampling method, introduction method). Therefore, a direct
10 comparison of the O_2/N_2 ratio or the O_2 molar fraction between the AIST and NIES scales, by a round-robin experiment of
11 the HPOs developed in this study, is required some time in the near future to quantify the differences in absolute values and
12 span of each gravimetric scale.

13 6.2 Determination of atmospheric O_2 and Ar molar fractions and comparison with previous data

14 The molar fractions for atmospheric O_2 and Ar were determined based on $\delta(\text{O}_2/\text{N}_2)$ and $\delta(\text{Ar}/\text{N}_2)$ values for air samples taken
15 at Hateruma Island in 2015. The $\delta(\text{O}_2/\text{N}_2)$ and $\delta(\text{Ar}/\text{N}_2)$ values were -62.8 per meg and -62.8 per meg, respectively. Using
16 the $(\text{O}_2/\text{N}_2)_{\text{ref}}$ and $(\text{Ar}/\text{N}_2)_{\text{ref}}$ ratios for AIST reference air, the $\delta(\text{O}_2/\text{N}_2)$ and $\delta(\text{Ar}/\text{N}_2)$ values were used to calculate the O_2/N_2
17 and Ar/N_2 ratios using equation (1) and (2). In 2015, the calculated O_2/N_2 and Ar/N_2 ratios for samples from Hateruma Island
18 were 0.2680761 ± 0.0000018 and 0.0119534 ± 0.0000009 , respectively. The molar fractions of O_2 and Ar (x_{O_2} and x_{Ar}) were
19 calculated using the aforementioned O_2/N_2 and Ar/N_2 ratios by using the equations below.

$$21 \quad x_{\text{O}_2} = K \times \frac{\text{O}_2/\text{N}_2}{(1 + \text{O}_2/\text{N}_2 + \text{Ar}/\text{N}_2)} \quad (8)$$

$$22 \quad x_{\text{Ar}} = K \times \frac{\text{Ar}/\text{N}_2}{(1 + \text{O}_2/\text{N}_2 + \text{Ar}/\text{N}_2)} \quad (9)$$

23
24 In these two equations, K is the sum of N_2 , O_2 , and Ar molar fractions in the air samples and was estimated to be $999567.8 \pm$
25 $0.1 \mu\text{mol mol}^{-1}$. To obtain this value, the molar fractions of Ne ($18.18 \mu\text{mol mol}^{-1}$), He ($5.24 \mu\text{mol mol}^{-1}$), CH_4 ($1.82 \mu\text{mol}$
26 mol^{-1}), Kr ($1.14 \mu\text{mol mol}^{-1}$), H_2 ($0.52 \mu\text{mol mol}^{-1}$), N_2O ($0.32 \mu\text{mol mol}^{-1}$), CO ($0.15 \mu\text{mol mol}^{-1}$) and Xe ($0.09 \mu\text{mol mol}^{-1}$)
27 reported by Tohjima et al. (2005) and CO_2 ($404.7 \mu\text{mol mol}^{-1}$) in 2015 were used. The CO_2 molar fraction was the average
28 CO_2 molar fraction measured using a mass spectrometer. The calculated O_2 and Ar molar fractions were $209339.1 \pm 1.1 \mu\text{mol}$
29 mol^{-1} and $9334.4 \pm 0.7 \mu\text{mol mol}^{-1}$, respectively. Standard uncertainties were estimated in accordance with the law of
30 propagation of uncertainties. In 2000, Tohjima et al. (2005) reported the atmospheric Ar molar fraction of $9333.2 \pm 2.1 \mu\text{mol}$
31 mol^{-1} (2005), whereas the value reported for air samples collected on Korea's Anmyeon Island in 2002 and at Niwot Ridge
32 in 2001 was $9332 \pm 3 \mu\text{mol mol}^{-1}$ (Park et al., 2004). Hence, our values for atmospheric Ar were in line previous reports.

1 **7 Conclusion**

2 In this study, we demonstrated that the deviation of mass readings of the sample cylinders is susceptible to temperature
3 differences between the sample and reference cylinders. The contribution degree of the temperature difference was -14.3 mg
4 K^{-1} . Our results also indicate that variations in mass readings due to temperature difference could be reduced to negligible
5 levels by obtaining mass readings at thermal equilibrium. A long time is required to reach thermal equilibrium. Since the
6 variations mainly depend on temperature differences rather than factors related to the adsorption phenomena (e.g., the
7 temperature of the cylinder and/or the humidity of ambient air), it was thus concluded that the variations in mass readings
8 were influenced solely by thermal effects.

9 We developed a preparation technique for the production of HPOs with atmospheric levels of CO_2 , Ar, O_2 , and N_2 . To
10 determine the O_2 molar fractions with standard uncertainties of less than $1 \text{ } \mu\text{mol mol}^{-1}$, repeatability in measuring the mass
11 readings of the sample cylinders was determined to be 0.82 mg . The impact of leakage or permeation of the source gases
12 through the cylinder valve, as well as change in buoyancy such as the expansion of the cylinder as a factor of the cylinder
13 inner pressure was evaluated. Additionally, the molar masses of the source gases, pure O_2 and pure N_2 , were determined based
14 on the abundance of their isotopes. The gravimetrically calculated standard uncertainties were in good agreement with the
15 standard deviation for the corresponding measured values. This indicates that the uncertainty calculations of the gravimetric
16 values for constituents performed in this study were accurate and valid.

17 Based on the HPOs prepared in this study, we determined molar fractions of atmospheric Ar and O_2 at Hateruma Island in
18 2015. These values were $9334.4 \pm 0.7 \text{ } \mu\text{mol mol}^{-1}$ and $209339.1 \pm 1.1 \text{ } \mu\text{mol mol}^{-1}$, for Ar and O_2 , respectively. The
19 atmospheric Ar molar fraction was in line with the values reported by Park ($9332 \pm 3 \text{ } \mu\text{mol mol}^{-1}$) and Tohjima (9333.2 ± 2.1
20 $\text{ } \mu\text{mol mol}^{-1}$) (Park et al., 2004; Tohjima et al., 2005).

22 **Acknowledgments**

23 This study was partly supported by funding from the Global Environment Research Coordination System from the Ministry
24 of the Environment, Japan. We express our gratitude to Noritsugu Tsuda, Nobukazu Oda, Fujio Shimano of Global
25 Environmental Forum, and Yasunori Tohjima of National Institute for Environmental Studies for their cooperation in
26 collecting air samples at Hateruma Island.

Sources	Atomic mass of nitrogen ^a		Atomic mass of oxygen ^a	
Atmosphere	14.006726(4)		15.999405(1)	
Source gases	14.006717(4)		15.999366(1)	

4

5 ^a Numbers in the parentheses represent the standard uncertainty in the last digits.

6 ^b Atomic mass and the standard uncertainty as determined by De Laeter et al. (2003).

7 ^c Abundance of the isotope and the standard uncertainty as determined using calculations for the absolute ¹⁵N/¹⁴N ratio
 8 obtained by Junk and Svec (1958).

9 ^d Abundance of the isotope and the standard uncertainty were calculated using ¹⁷O/¹⁶O = 12.08 ‰ and ¹⁸O/¹⁶O = 23.88 ‰ vs.
 10 the VSMOW as determined by Barkan and Luz (2005). The absolute isotopic ratio for VSMOW and the standard uncertainty
 11 were determined by Li et al. (1988) for ¹⁷O/¹⁶O and Baertschi (1976) for ¹⁸O/¹⁶O.

12 ^e Isotopic ratio is defined as the difference in the corresponding atmospheric value (AIST reference air) measured using a
 13 mass spectrometer. Numbers following the symbol ± denote the standard uncertainty.

14

1

2 **Figure 1** Changes in mass readings of sample cylinders plotted against the time elapsed after evacuation of the cylinder and
 3 filling of source gases. The mass readings were obtained using the weighing system. Deviation of the mass reading is
 4 expressed as the change in amount from the equilibrium value, which was defined as the mass reading when the standard
 5 deviation of the values remained constant for two or more hours.

^a Numbers following the symbol ± denote the standard uncertainty.

^b Values were calculated using the absolute O₂/N₂ and Ar/N₂ in AIST reference air as described in section 5.1.

Table 3. Typical contribution of each source of uncertainty (including the mass of the source gas, molar mass, and purity) to the standard uncertainties obtained for the molar fractions of N₂, O₂, Ar, and CO₂ in the HPO.

Constituent	Uncertainty source, $\mu\text{mol mol}^{-1}$			Combined standard uncertainty, $\mu\text{mol mol}^{-1}$
	Mass of source gas ^a	Molar mass ^b	Purity ^c	
N ₂	0.77	0.11	0.05	0.77
O ₂	0.63	0.03	0.03	0.63
Ar	0.56	0.13	0.02	0.58
CO ₂	0.025	0.006	0.011	0.028

^a The values were calculated in the procedure described in section 4.3.

^b The values were calculated in the procedure described in section 4.2.

^c The values were calculated in the procedure described in section 4.1.

Table 4. Impurities in source gases for preparation of HPOs

Impurity	Source gases, $\mu\text{mol mol}^{-1}$			
	CO ₂	Ar	O ₂	N ₂
N ₂	0.9 ± 0.5	0.12 ± 0.07	0.12 ± 0.07	-
O ₂	0.3 ± 0.1	0.5 ± 0.3	-	0.05 ± 0.03 0.05 ± 0.03
Ar	-	-	0.089 ± 0.052	0.28 ± 0.01 0.32 ± 0.03
CO ₂	-	0.002 ± 0.001	0.124 ± 0.004	0.002 ± 0.001
H ₂ O	4.8 ± 2.7	0.05 ± 0.03	0.05 ± 0.03	0.05 ± 0.03
CH ₄	0.6 ± 0.3	0.005 ± 0.003	0.005 ± 0.003	0.005 ± 0.003
CO	-	0.04 ± 0.02	0.04 ± 0.02	0.04 ± 0.02
H ₂	2.2 ± 1.3	-	-	-
Purity	999991.3 ± 3.1	999999.3 ± 0.3	999999.6 ± 0.1	999999.8 ± 0.1 999999.6 ± 0.1 999999.5 ± 0.1

Numbers following the symbol \pm denote the standard uncertainty.

“-” represents the constituents which were not measured.

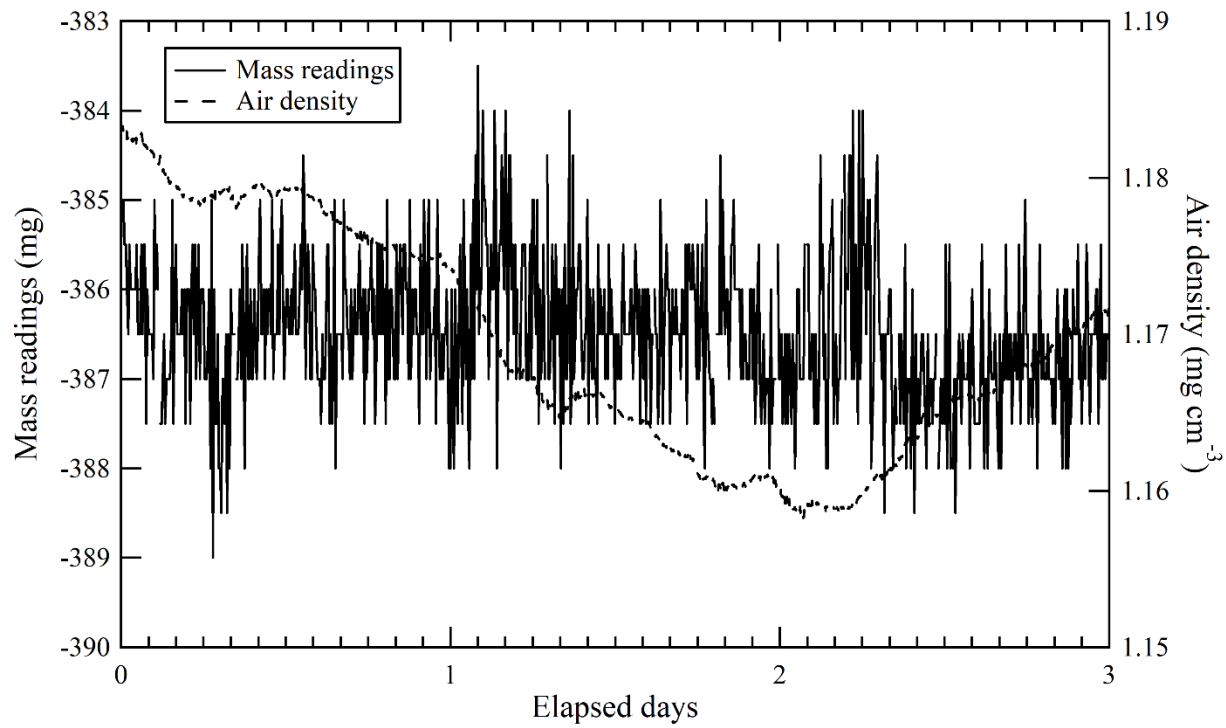

Figure 4 Repeatability of mass readings obtained for the sample cylinders and ambient air density for three days. Solid and dashed lines represent mass readings and ambient air density, respectively

Table 5. $\delta(^{15}\text{N}^{14}\text{N}/^{14}\text{N}^{14}\text{N})_{\text{HPO_meas}}$, $\delta(^{17}\text{O}^{16}\text{O}/^{16}\text{O}^{16}\text{O})_{\text{HPO_meas}}$, $\delta(^{18}\text{O}^{16}\text{O}/^{16}\text{O}^{16}\text{O})_{\text{HPO_meas}}$, $\delta(^{16}\text{O}^{16}\text{O}/^{14}\text{N}^{14}\text{N})_{\text{HPO_meas}}$, $\delta(^{36}\text{Ar}/^{40}\text{Ar})_{\text{HPO_meas}}$ and $\delta(^{40}\text{Ar}/^{14}\text{N}^{14}\text{N})_{\text{HPO_meas}}$ measured by the mass spectrometer. $\delta(\text{O}_2/\text{N}_2)_{\text{HPO_meas}}$ and $\delta(\text{Ar}/\text{N}_2)_{\text{HPO_meas}}$ calculated using equations (3) and (4), and differences between $\delta(\text{O}_2/\text{N}_2)_{\text{HPO_meas}}$ and $\delta(^{16}\text{O}^{16}\text{O}/^{14}\text{N}^{14}\text{N})_{\text{HPO_meas}}$ are also shown.

Cylinder number	$\delta(^{15}\text{N}^{14}\text{N}/^{14}\text{N}^{14}\text{N})_{\text{HPO_meas}}$	$\delta(^{17}\text{O}^{16}\text{O}/^{16}\text{O}^{16}\text{O})_{\text{HPO_meas}}$	$\delta(^{18}\text{O}^{16}\text{O}/^{16}\text{O}^{16}\text{O})_{\text{HPO_meas}}$	$\delta(^{16}\text{O}^{16}\text{O}/^{14}\text{N}^{14}\text{N})_{\text{HPO_meas}}$	$\delta(\text{O}_2/\text{N}_2)_{\text{HPO_meas}}$	$\delta(\text{O}_2/\text{N}_2)_{\text{HPO_meas}} - \delta(^{16}\text{O}^{16}\text{O}/^{14}\text{N}^{14}\text{N})_{\text{HPO_meas}}$	$\delta(^{36}\text{Ar}/^{40}\text{Ar})_{\text{HPO_meas}}$	$\delta(^{40}\text{Ar}/^{14}\text{N}_2)_{\text{HPO_meas}}$	$\delta(\text{Ar}/\text{N}_2)_{\text{HPO_meas}}$
