6 **Abstract**

7 Knowledge on the refractive index of ambient aerosol can help reduce the uncertainties in
8 estimating aerosol radiative forcing. A new method is proposed to retrieve the size-resolved real part
9 of RI (RRI). Main principle of deriving the RRI is measuring the scattering intensity by single particle
10 soot photometer of size-selected aerosol. This method is validated by a series of calibration
11 experiments using the components of known RI. The retrieved size-resolved RRI cover a wide range
12 from 200nm to 450nm with uncertainty less than 0.02. Measurements of the size resolved real part of
13 the aerosol refractive index can improve the understanding of the aerosol radiative effects.

14 **1 Introduction**

15 Aerosols exert significant influence on the earth energy budget by scattering and absorbing
16 radiation (Ramanathan and Carmichael, 2008). There still remain great uncertainties when estimating
17 the aerosol effective radiative forcing (RF) (Ghan and Schwartz, 2007) and an accurate estimation of
18 the aerosol optical properties can help reduce the RF variations. The optical properties of the ambient
19 aerosol particles are determined by their particle size and complex refractive index (RI, $m=n+ki$)
20 (Bohren and Huffman, 2007; Levoni et al., 1997). Despite that the ambient aerosol particle size
21 distribution can be measured with high accuracy (Wiedensohler et al., 2012), an accurate measurement
22 of the ambient aerosol RI remains challenging. The RI is also widely used in remote sensing
23 (Redemann et al., 2000; Dubovik, 2002; Zhao et al., 2017) and atmospheric modelling (Ghan and
24 Schwartz, 2007; Kuang et al., 2015) because the aerosol single scattering albedo (SSA) and aerosol
25 scattering phase function are highly related with the RI. At the same time, a small uncertainty in the
26 real part of the RI (RRI) can lead to great uncertainties when estimating the aerosol RF. Zarzana et al.
27 (2014) finds that a variation of 0.003 in RRI can lead to uncertainties of 1% in RF for non-absorbing
28 ammonium sulfate particles. Moise et al. (2015) estimates that the RF will increase 12% when the RRI
29 varies from 1.4 to 1.5. Valenzuela et al. (2018) also reports an uncertainty of 7% with the uncertainties

30 of RRI of 0.1 in RRI. Therefore, it is pressing that the uncertainties of the RI be reduced when
31 estimating the RF.

32 Many methods were proposed to derive the RRI. The RRI can be estimated by linear volume
33 average of the known aerosol chemical components by

34
$$n = \sum_i f_i n_i \quad (1)$$

35 where f_i and n_i is the volume fraction and known partial refractive index of i th component (Wex et
36 al., 2002;Hand and Kreidenweis, 2002;Hanel, 1968;Liu and Daum, 2008). The aerosol RRI can also
37 be calculated by partial molar refraction approach (Stelson, 1990;Hu et al., 2012) which is essentially
38 consistent with the linear volume method (Liu and Daum, 2008). The ambient aerosol RRI can be
39 derived by synthetically using the radiative transfer calculations and the ground-based solar extinction
40 and scattering measurements (Wendisch and Hoyningen-Huene, 1994, 1992). Sorooshian et al. (2008)
41 developed a method to measure the aerosol RRI based on the differential mobility analyzer (DMA)
42 and an optical particle counters. The RRI is retrieved from the known particle size from the DMA and
43 the aerosol scattering intensity from the Optical Particle Counter (OPC) for aerosol particles larger
44 than 500nm. The Scanning Mobility Particle Sizer (SMPS) and OPC is used in combination to derive
45 the RRI by aligning the particle size distributions in the instrument overlap regions (Hand and
46 Kreidenweis, 2002;Vratolis et al., 2018). The aerosol effective RRI is also retrieved by applying Mie
47 scattering theory to the aerosol particle number size distribution, aerosol bulk scattering coefficient
48 and aerosol absorbing coefficient data (Cai et al., 2011;Liu and Daum, 2000). Spindler et al. (2007)
49 retrieved the aerosol RRI value by using the cavity ring-down spectroscopy to measuring the scattering
50 and absorbing properties of bulk aerosols. Eidhammer et al. (2008)) measured the light scattering at
51 different angles and retrieved the RRI. Similarly, the aerosol RRI is retrieved by measuring the aerosol
52 phase function (Barkey et al., 2007). Recently, a method by using the single particle mass spectrometry
53 is proposed to measure the aerosol RRI (Zhang et al., 2015). At the same time, aerosol time-of-flight
54 mass spectrometer is proved to be capable of measuring the aerosol RRI (Moffet et al., 2008). The
55 aerosol RRI can also be retrieved from the Mie spectroscopy by using the optical tweezers in the
56 laboratory (Shepherd et al., 2018).

57 Up to now, there is no information in the literature of the size-resolved ambient aerosol RRI over
58 the diameter range between 200nm and 500nm where the aerosol scattering coefficients contributes to
59 the total scattering coefficients most (Tao et al., 2017;Kuang et al., 2018). All the instruments

60 mentioned above can only measure the total equivalent aerosol RRI or aerosol RRI at a given diameter.
61 However, many studies show that aerosol of different diameter shares different properties such as
62 shape (Zhang et al., 2016; Peng et al., 2016), density (Qiao et al., 2018), aerosol hygroscopicity (Wang
63 et al., 2017) and most importantly, the chemical components (Liu et al., 2014; Hu et al., 2012). Thus,
64 there might be significant variations in the aerosol RRI for aerosols of different diameter because the
65 aerosol RRI is highly related to the aerosol density (Liu and Daum, 2008) and chemical components
66 (Stelson, 1990). On the other way round, information of the size-resolved aerosol RRI can help to
67 study the chemical information and the aging process of aerosols among different diameters. Therefore,
68 measurement of the size-resolved aerosol RRI is necessary.

69 In this study, a novel method is proposed to measure the size-resolved ambient aerosol RRI by
70 using a DMA in tandem with a single particle soot photometer (SP2). The principle of the system is
71 using the SP2 to measure the scattering properties of size-selected aerosols. Knowing the aerosol
72 diameter and corresponding scattering intensity, the size-resolved aerosol RRI can be retrieved based
73 on the Mie scattering theory. This proposed method can measure the ambient aerosol RRI over a wide
74 size range with high accuracy. The measurement system is employed in a field campaign in the North
75 China Plain and the corresponding results are further discussed.

76 The structure of this manuscript is as follows: section 2 provides the instruments setup and details
77 of the instrument. The method of retrieving the size-resolved aerosol RRI is given in section 3. Section
78 4 shows the discussions about the uncertainties of the proposed method and field measurements results
79 of the size-resolved aerosol RRI. Conclusions come at the last part.

80 **2 Instrument**

81 **2.1 Instrument Setup**

82 The instrument setup is schematically shown in fig. 1(a). Firstly, the dried sample aerosols are
83 guided to a X-ray soft diffusion charger and then lead to a DMA (Model 3081, TSI, USA). The quasi-
84 monodisperse aerosols that pass through the DMA at a given diameter are then drawn into a SP2 to
85 measure the aerosol scattering properties with a flow ratio of 0.12 lpm and a condensation particle
86 counter (CPC, Model 3776, TSI, USA) to count the aerosol number concentration with a flow ratio of
87 0.28 lpm respectively. Thus, the sample flow (Q_a) of the DMA is 0.4 lpm. Accordingly, the sheath
88 flow (Q_{sh}) of the DMA is 4 lpm. The DMA is set to scan the aerosols diameter from 12.3 to 697 nm

89 over a period of 285s and repeats after a pause of 15s. Thus, the combination of DMA, CPC and SP2
 90 can provide the aerosol PNSD and size-resolved RRI every 5 minutes.

91 On 8th, June, 2018, the measurement system was employed at the filed measurement of
 92 AERONET station of BEIJING_PKU (N39°59', E116°18') to test the reliability of retrieving the
 93 ambient size-resolved RRI. This measurement site locates on the north west of the city of Beijing,
 94 China and is about 1.8 km north of the Zhongguancun, Haidian District, which is one of the busiest
 95 areas in Beijing. It is surrounded by two main streets: Zhongguancun North Street to the west and
 96 Chengfu Road to the south. This site can provide representative information of the urban roadside
 97 aerosols (Zhao et al., 2018).

98 2.2 DMA

99 When a voltage (V) is applied to the DMA, only a narrow size range of aerosol particles, with the
 100 same electrical mobility (Z_p) can pass through the DMA (Knutson and Whitby, 1975). The Z_p is
 101 expressed as:

$$102 \quad Z_p = \frac{Q_{sh}}{2\pi VL} \ln\left(\frac{r_1}{r_2}\right) \quad (2)$$

103 where Q_{sh} is the sheath flow rate; r_1 is the outer radius of annular space and r_2 is the inner radius of the
 104 annular space. The transfer function refers to the probability that a particle with a certain electrical
 105 mobility can pass through the DMA. For a given V, the transfer function is triangular-shaped, with the
 106 peaking value of 100% and a half width (HW) of

$$107 \quad \Delta Z_p = Z_p \frac{Q_a}{Q_{sh}} \quad (3).$$

108 The aerosol Z_p , which is highly related to the aerosols diameter (D_p) and the number of elementary
 109 charges on the particle (n), is defined as:

$$110 \quad Z_p = \frac{neC(D_p)}{3\pi\mu D_p} \quad (4)$$

111 where e is the elementary charge; μ is the gas viscosity coefficient, $C(D_p)$ is the Cunningham slip
 112 correction that is defined by:

$$113 \quad C = 1 + \frac{2\tau}{D_p} \left(1.142 + 0.558e^{-\frac{0.999D_p}{2\tau}}\right) \quad (5)$$

114 where τ is the gas mean free path.

115 Based on the discussion above, the aerosols that pass through the DMA with the same Z_p , can have
 116 different D_p and different elementary charges.

117 **2.3 SP2**

118 The SP2 is a widely used instrument that can measure the optical properties of every single particle.
119 The measurement principle and instrumental setup of the SP2 have been discussed in detail previously
120 (Stephens et al., 2003; Schwarz et al., 2006) and will be briefly described here. When the sample
121 aerosol particles pass through the continuous Nd:YAG laser beam at 1064nm with power about 1
122 mW/cm², eight sensors distributed at four directions are synchronously detecting the emitted or
123 scattered light by using avalanche photo-detector (APD) at different angles (45° and 135°). For each
124 direction, the two APDs sample the same signal with different sensitivities to get a wider measurement
125 range. The low gain channels are less sensitive to the measured signal and can be used to measure the
126 stronger signal of larger particles. In accordance, the high gain channels are more sensitive to the
127 measured signal, and can be used to measure the weaker signal of smaller particles. The optical head
128 of the SP2 is shown schematically in fig. 1(b).

129 In this study, we utilize signals from four channels of the SP2: two of them measure the scattering
130 signals and another two measure the incandescent light between 350 nm and 800 nm. The peak height
131 (H) of the incandescence signals is used to infer whether the sampled aerosol contains the black carbon
132 (BC). If the H of the incandescence signal is larger than 500, the sample aerosol contains the BC and
133 the scattering signals should deviate from the signals of pure scattering aerosol. Those sample aerosols
134 are ruled out when dealing with the aerosol scattering signals.

135 **3 Methodology**

136 **3.1 Scattering strength measured by the SP2**

137 From fig. 1(b), the APDs of the SP2 receive signals that were scattered by the sampled aerosols
138 from the directions at 45° and 135°. Thus, the scattering intensity (S) measured by the APD can be
139 expressed as:

$$140 \quad S = C \cdot I_0 \cdot \sigma \cdot (PF_{45^\circ} + PF_{135^\circ}) \quad (6),$$

141 where I_0 is the laser's intensity; σ is the scattering coefficient of the sampled aerosol, PF_{45° and
142 PF_{135° are scattering phase function at 45° and 135° respectively of the sampled aerosols; and C is
143 constant that is determined by the distance from the aerosol to the APD and the area of the APD. The
144 scattering intensity of the aerosol is recorded as the H of the scattering signals by SP2. Therefore, the
145 SP2 can be used as a powerful tool to measure the scattering signals of the sampled aerosol and the

146 influence of the BC on the aerosol scattering properties can be avoided. Based on the Mie scattering
147 theory, σ , PF_{45° and PF_{135° are determined by the size and RRI of the aerosol.

148 The amount of scattering signals from the sample aerosol varies with the diameter and RRI of the
149 aerosol (Bohren and Huffman, 2007). The scattering intensity at different aerosol diameter and RRI is
150 calculated based on equation (6) and shown in fig. 2. The C is assumed to be 1 here. From fig. 2, we
151 can see that the aerosol scattering intensity increases homogeneously with the increasing aerosol RRI
152 at a given D_p , which makes it possible to retrieve the aerosol RRI when the D_p and the scattering
153 intensity are known.

154 Bridging the scattering H values measured by the SP2 scattering channel and the scattering
155 intensity defined by equation 6 is achieved by calibrating the SP2 with ammonium sulfate. The
156 instrument setup of the calibration procedure is the same as that described in section 2.2.1. The
157 diameters of the aerosols passing through the DMA are manually changed from 100 to 450nm with a
158 step of 10nm. For each diameter, the scattering H value and incandescence signal of every particle are
159 analyzed. When calibrating, there is no aerosol whose incandescence signal exceeds 1000, which
160 means that the SP2 works stably and the incandescence signal channel can well distinguish the BC
161 containing aerosols.

162 After the calibration, the size-resolved RRI can be retrieved with known aerosol diameter selected
163 by DMA and the corresponding aerosol scattering H values measured by SP2.

164 3.2 Multiple Charging

165 Fig. S2 gives the aerosols scattering H probability distribution under different aerosol diameter.
166 For each diameter, the distributions of the scattering H may have more than one mode for both the high
167 gain and low gain channels. The following discussions would give explanation about the multiple
168 mode distributions of H.

169 For each mode, the number of recorded aerosol particles at a given H is fit by the log-normal
170 distribution function:

$$171 \quad N(H) = \frac{N_0}{\sqrt{2\pi}\log(\sigma_g)} \cdot \exp\left[-\frac{\log(H)-\log(H_0)}{2\log^2(\sigma_g)}\right] \quad (7)$$

172 Where σ_g is the geometric standard deviation; H_0 is the geometric standard mean H and N_0 is the
173 number concentrations for a peak mode. The geometric standard deviation is highly related to the half
174 width of the transfer function (equation 3) and the H_0 is discussed below in detail.

175 The H_0 values of each mode at different diameters are labeled with different markers in fig. 2. The
176 σ_g is fitted to be a small range at 1.182 ± 0.02 for different mode and different aerosol diameter. In
177 the following discussion, we conclude that the different PH_0 values in fig. 3 represent that the aerosols
178 are charged with different number of elementary charges. Based on the Mie scattering theory (Bohren
179 and Huffman, 2007), the scattering intensity increases with increasing D_p , which imply that the H_0
180 should increase with the increment of D_p . Thus, the black square markers in fig.2 represent the aerosols
181 that are singly charged. At the same time, the relationships between the H_0 and D_p can be interpolated.

182 Other colored markers represent that the aerosols have more than one charge. We calculated the
183 corresponding diameter of the aerosols that share the same Z_p but different charges at the given D_p by
184 the DMA (\widetilde{D}_p). Then the corresponding H_0 at \widetilde{D}_p are calculated and shown in dashed line in fig.2.
185 From fig.2, the calculated H_0 shows good consistence with the measured H_0 .

186 From the discussion above, we conclude that the SP2 detect those ammonium sulfate aerosols
187 with the diameter larger than 160nm. However, the ambient aerosol RRI is always lower than that of
188 ammonium sulfate (Liu and Daum, 2008), thus the lower detecting limit of the ambient scattering
189 aerosols should be larger than 160nm. The measured H_0 of the SP2 scattering low gain channel signals
190 are shown in fig. S2. From fig. S2, the same results can be deduced as those of the high gain channel
191 signals.

192 Fig. 4(a) gives the relationships between the calculated scattering intensity and the SP2 aerosol
193 scattering H at different diameter. When calculating the scattering intensity, the RRI value of
194 ammonium sulfate is set to be 1.521. We can see that the aerosol scattering intensity shows good
195 consistence with the peak height ($R^2=0.9992$).

196 Furthermore, the RRI of the scattering aerosol at a given diameter can be retrieved using the
197 corresponding scattering H .

198 3.3 Validation of the calibration

199 Ammonium chloride is used to validate the method of deriving the RRI from SP2. The RRI value
200 of ammonium chloride is 1.642. The scattering H of the ammonium chloride under different diameters
201 are measured and analyzed. Fig. 4(b) shows the comparison between the measured scattering high gain
202 peak height and the theoretical peak height at different aerosols diameter. Results show that the
203 measured peak height and the calculated ones are well correlated with $R^2=0.9994$, which means that

204 the DMA and SP2 can be used to derived the aerosol RRI with high accuracy.

205 Fig. S3 gives the corresponding results of the scattering low gain channel. In fig. S3, the
206 relationship between the aerosol scattering peak height of the low gain channel and the scattering
207 strength is determined. At the same time, the comparison between the measured peak height and the
208 calculated peak height shows good consistence too.

209 **4 Results and Discussion**

210 **4.1 Field Measurements**

211 Figure 5 shows the measured average probability distribution of the ambient size-resolved RRI
212 and the measured mean PNSD. From fig. 5, we can see that the derived RRI is 1.46 ± 0.02 and doesn't
213 vary significantly with diameter between 199 nm and 436 nm. The measured aerosol PNSD during the
214 measurement has a maximum of 26400 \#/cm^3 at 107 nm. Based on the measured PNSD and the
215 measured RRI, the size distribution of the scattering coefficient is calculated based on the Mie
216 scattering theory. The results in fig. 5 show that the measured RRI diameter range covers most of the
217 aerosol that contributes significantly to the aerosol scattering properties. Thus, the derived size-
218 resolved RRI of this range is representative of the ambient aerosols scattering properties.

219 **4.2 Uncertainty analysis**

220 The factors that influence the accuracy of retrieving RRI include the aerosols scattering H
221 measured by SP and the aerosol diameter selected by DMA.

222 The uncertainties of the selected diameter by DMA is well characterized based on equation 2 and
223 3. The uncertainties from the DMA transfer function can be avoided by fitting the scattering H using
224 the log-normal distribution function. However, the uncertainties of the measured H from the SP2
225 remain unknown. The HW of the transfer function is 0.1 times the scanning diameter, which means
226 that the geometric standard deviation of the aerosol PNSD selected by the DMA is estimated to be
227 1.102. At the same time, the measured geometric standard deviation of the measured H mode by SP2
228 is 1.182. Thus, the geometric standard deviation of the measured H from the SP2 is estimated to be
229 1.073, whose corresponding uncertainties is 6.8%.

230 The uncertainties of the retrieved RRI to the variations in the measured H are analyzed using the
231 Mie scattering theory and the corresponding results are shown in fig. 6. The variations in RRI increase
232 with the increment of RRI but decrease with the increment of the D_p . For most ambient aerosols, the

233 RRI ranges from 1.4 to 1.5 and corresponds to a variation in RRI of 0.015.

234 Table 1 lists the retrieved ammonium chloride RRI under different diameter. The absolute
235 difference between the retrieved RRI and theoretical values is always smaller than 0.02 regardless of
236 the particle diameter, which means that the measured RRI is in line with the theoretical one. Thus, we
237 conclude that the uncertainty of the retrieved RRI is within 0.02.

238 **5 Conclusions**

239 Knowledge on the microphysical properties of ambient aerosol is import for better evaluating
240 their radiative forcing. The aerosol RRI is a key factor that determines the aerosol scattering properties.
241 In this study, a new method to measure the ambient aerosol RRI is developed by synthetically using a
242 DMA in tandem with a SP2. This method can continuously measure the size-resolved RRI over a wide
243 range between 198 nm and 426 nm with an accuracy of 0.02. At the same time, it is free from the
244 influence of the BC containing aerosols.

245 The basic principle of measuring the size-resolved RRI is to select the aerosols at a certain
246 diameter by the DMA and measure the corresponding scattering intensity by the SP2. The relationship
247 between the aerosols scattering intensity and the peak height of the scattering signal channels are
248 determined by calibrating the SP2 using ammonium sulfate (RRI=1.521).

249 The method is validated by using the ammonium chloride with the RRI of 1.642 as sample aerosol
250 and the corresponding derived size-resolved RRI is 1.642 ± 0.02 .

251 This instrument is employed at a field measurement at the AERONET PKU stating, the size-
252 resolved RRI of the ambient aerosols is 1.46 and doesn't show significant variation among the diameter.
253 The corresponding aerosol diameter range, which can be detected by SP2 to derive the RRI, covers
254 most of the aerosol scattering. Thus, the derived size-resolved RRI of this range can be used as a good
255 representative of the ambient aerosols scattering properties.

256

257 **Data availability.** The measurement data involved in this study are available upon request to the
258 authors.

259

260 **Author contributions.** Gang Zhao and Chunsheng Zhao designed the experiments; Gang Zhao and
261 Weilun Zhao conducted the measurements; Chunsheng Zhao and Gang Zhao discussed the results and
262 wrote the manuscript.

263

264 **Competing interests.** The authors declare that they have no conflict of interest.
