## 10 Abstract

11 Due to the important contribution of nitrous acid (HONO) to OH radicals in the  
12 atmosphere, various technologies have been developed to measure HONO. Among  
13 them, wet denuder/ion chromatography (WD/IC) is a widely used measurement method.  
14 Here, we found interferences with HONO measurements by WD/IC based on a  
15 comparison study of concurrent observations of HONO concentrations using a WD/IC  
16 instrument (Monitor for AeRosols and Gases in ambient Air, MARGA) and long-path  
17 absorption photometer (LOPAP) at the Station for Observing Regional Processes of the  
18 Earth System (SORPES) in eastern China. The measurement deviation of the HONO  
19 concentration by the MARGA instrument, as a typical instrument of WD/IC, is affected  
20 by two factors. One is the change in denuder pH influenced by acidic and alkaline gases  
21 in the ambient atmosphere, which can affect the absorption efficiency of HONO by the  
22 wet denuder to underestimate the HONO concentration up to 200% in lowest pH. The  
23 other is the reaction of NO<sub>2</sub> oxidizing SO<sub>2</sub> to form HONO in the denuder solution to  
24 overestimate the HONO concentration, which can be improved up to 400% in denuder  
25 solutions with highest pH values due to ambient NH<sub>3</sub>. These processes are in particulate  
26 important in polluted east China, where is suffered from the high concentrations of SO<sub>2</sub>,  
27 NH<sub>3</sub> and NO<sub>2</sub>. The overestimation induced by the reaction of NO<sub>2</sub> and SO<sub>2</sub> is expected  
28 to be growing important with the potentially increased denuder pH due to the decrease  
29 of SO<sub>2</sub>. We further established a method to correct the HONO data measured by a  
30 WD/IC instrument such as the MARGA. In case a large amount WD/IC techniques  
31 based instruments are deployed with the main target to monitor the water soluble  
32 composition of PM<sub>2.5</sub>, our study can help to obtain a long-term multi-sites database of  
33 HONO to assess the role of HONO in atmospheric chemistry and air pollution in east  
34 China.

## 35 1. Introduction

36 Since the first detection of nitrous acid (HONO) in the atmosphere in 1979 (Perner and  
37 Platt, 1979), HONO has drawn much attention due to its important contribution to OH

38 radicals, which are the primary oxidants in the atmosphere (Kleffmann, 2007). It has  
39 been realized that the photolysis of HONO is the most significant OH source in the  
40 morning when other OH sources, such as the photolysis reactions of O<sub>3</sub> and  
41 formaldehyde, are still weak (Kleffmann, 2007;Platt et al., 1980). In addition,  
42 unexpectedly high HONO concentrations have been observed in the daytime and are  
43 believed to be a major OH source even during the daytime (Kleffmann et al.,  
44 2005;Michoud et al., 2014;Sorgel et al., 2011). Currently, the source of daytime HONO  
45 is still a challenging topic under discussion.

46 Because of the important role of HONO in atmospheric chemistry and the knowledge  
47 gap with regards to its sources, various techniques have been developed to detect the  
48 HONO concentration in ambient air or in a smog chamber. Generally, on-line HONO  
49 analyzers can be divided into chemical methods and optical methods. The chemical  
50 methods include wet denuder-ion chromatography (WD/IC) (Acker et al., 2004;Febo  
51 et al., 1993), long-path absorption photometer (LOPAP) analysis(Heland et al., 2001),  
52 and chemical ionization mass spectrometry (CIMS) (Lelièvre et al., 2004). The optical  
53 methods include differential optical absorption spectroscopy (DOAS)(Perner and Platt,  
54 1979) and incoherent broadband cavity absorption spectroscopy (IBBCEAS) (Wu et al.,  
55 2014).

56 WD/IC is a widely used measurement method due to its simple design, low price, and  
57 high sensitivity (Zhou, 2013). In a WD/IC instrument, HONO is absorbed by the  
58 solution, converted into nitrite by the denuder and then quantified by ion  
59 chromatography. The ambient HONO concentration is calculated from the  
60 concentration of nitrite and volumes of the sampled air and absorption solution. Using  
61 this method, a large number of studies have been performed to study the variation in  
62 HONO and its sources in the atmosphere. For example, Trebs et al. (2004) reported the  
63 HONO diurnal variation in the Amazon Basin and found relatively high HONO  
64 concentrations during the daytime. Using WD/IC, Su et al. (2008a);Su et al. (2008b)  
65 reported the variation characteristics of HONO in the Pearl River Delta and found that  
66 the heterogeneous reaction of NO<sub>2</sub> on the ground surface is the major HONO source.

67 Nie et al. (2015) evaluated the enhanced HONO formation from the biomass burning  
68 plumes observed in June, which is the intense biomass burning season in the Yangtze  
69 River Delta (YRD) in China. Makkonen et al. (2014) reported a one-year HONO  
70 variation pattern at the Station for Measuring Ecosystem-Atmosphere Relations  
71 (SMEAR) III, a forest station in Finland. Recently, abundant ambient particulate nitrite  
72 levels were also measured by WD/IC (VandenBoer et al., 2014).

73 However, many studies found that the HONO sampling procedures may have  
74 introduced unintended artifacts due to NO<sub>2</sub> and other atmospheric components will  
75 generate a series of chemical reactions in the sampling tube to generate HONO (Heland  
76 et al., 2001; Kleffmann and Wiesen, 2008). For example, NO<sub>2</sub> will heterogeneously  
77 react with H<sub>2</sub>O on the sampling tube wall to produce HONO (Heland et al., 2001; Zhou  
78 et al., 2002). This interference may be related to the length of the sampling tube and the  
79 relative humidity in the atmosphere (Su et al., 2008a). Recent studies have shown that  
80 NO<sub>2</sub> reacts with atmospheric aerosols such as black carbon, sand and hydrocarbons  
81 under certain conditions to produce HONO (Monge et al., 2010; Su et al., 2008a; Nie et  
82 al., 2015; Gutzwiller et al., 2002). Therefore, in the presence of high concentrations of  
83 aerosols, this reaction may lead to an enhancement of measurement interferences for  
84 the WD/IC system. In addition, when an alkaline solution, such as sodium carbonate,  
85 was used as the wet-denuder absorbing liquid for sampling HONO, artifact nitrous acid  
86 will be produced by the reaction between NO<sub>2</sub> and SO<sub>2</sub> (Spindler et al., 2003; Jongejan  
87 et al., 1997). Spindler et al. (2003) quantified the artifact HONO on an alkaline K<sub>2</sub>CO<sub>3</sub>  
88 surface with a pH of 9.7 in laboratory experiments. However, their results were only  
89 applicable for concentrated alkaline stripping solution (1mM K<sub>2</sub>CO<sub>3</sub>), which limited the  
90 application for quantifying the artifact HONO by the other WD/IC instrument with  
91 different denuder solution (Spindler et al., 2003; Su et al., 2008a). As an alternative,  
92 Genfa et al. (2003) used H<sub>2</sub>O<sub>2</sub> as the absorption liquid to absorb HONO. Since H<sub>2</sub>O<sub>2</sub>  
93 can rapidly oxidize the produced S(IV) to sulfate, and interrupt the reaction pathway of  
94 NO<sub>2</sub> and SO<sub>2</sub> to form NO<sub>2</sub><sup>-</sup>, which will eliminate the measurement error.

95 Though many efforts was conducted on the interferences of WD/IC, an intercomparison

96 between WD/IC and a technology with less interference is still needed in the field  
97 observation(Zhou, 2013). Only limited studies have been conducted on field  
98 comparisons between WD/IC and other reliable technologies. Moreover, the  
99 performance of WD/IC for HONO measurement is quite different under different  
100 environmental conditions. For example, Acker et al. (2006) showed a suitable  
101 correlation between WD/IC and coil sampling/HPLC during a HONO intercomparison  
102 campaign in an urban area of Rome ( $r^2=0.81$ , slope=0.83). Su et al. (2008b) found that  
103 WD/IC, on average, overestimated the HONO concentration by 1.2 times compared to  
104 the LOPAP measurement. However, when the same system was used for comparative  
105 observations in Beijing, the HONO concentration from the WD/IC measurement was  
106 overestimated by approximately 2 times (Lu et al., 2010). This phenomenon also  
107 indicates that the performance of WD/IC in the measurement of HONO is  
108 environmentally dependent.

109 To solve the complex atmospheric pollution problem in eastern China, a large number  
110 of two-channel WD/IC instruments represented by Monitor for AeRosols and Gases in  
111 ambient Air, MARGA) instruments was widely used to obtain aerosol composition  
112 information, as well as acid trace gas levels, including HONO(Stieger et al., 2018).  
113 Those database will greatly improve the understanding of air pollution in China.  
114 However, the application of HONO data was limited because of the measurement  
115 uncertainty. Therefore, the major purpose of this study is to try to evaluate the  
116 measurement uncertainty of WD/IC and increase reliability of HONO database  
117 obtained by MARGA or similar instruments. For the purpose, a MARGA and more  
118 accurate equipment (LOPAP) were used to simultaneously measure the HONO  
119 concentration at the Station for Observing Regional Processes of the Earth System  
120 (SORPES) in the YRD of East China. We evaluated the performance of the WD/IC  
121 instrument in measuring HONO concentrations and analyzed the source of  
122 measurement inference based on the atmospheric composition data from SORPES.  
123 Based on the understanding of the interference factors, a correction function was given  
124 to correct the HONO data measured by MARGA.

125 **2. Experiment**

126 **2.1 Observation site**

127 The field-intensive campaign was conducted from December 2015 to January 2016 at  
128 the SORPES station in the Xianlin campus of Nanjing University (Ding et al., 2016).  
129 SORPES station is a regional background site located on top of a hill (118°57'10" E  
130 and 32°07'14" N; 40 m a.s.l.), eastern suburb, approximately 20 km from downtown  
131 Nanjing. The station is an ideal receptor for air masses from the YRD with little  
132 influence from local emissions and urban pollution from Nanjing. Detailed information  
133 about SORPES can be found in Ding et al. (2016).

134 **2.2 Instrumentation**

135 The fine particulate matter (PM<sub>2.5</sub>) and trace gas (SO<sub>2</sub>, O<sub>3</sub>, NO<sub>x</sub>, and NO<sub>y</sub>) levels were  
136 measured by a set of Thermo Fisher analyzers (TEI,5030i, 43i, 49i, 42i, and 42iy). The  
137 MoO convertor of NO<sub>x</sub> analyzer was replaced by a blue light convertor to avoid the  
138 NO<sub>2</sub> measurement interference (Xu et al., 2013). The water soluble ions of PM<sub>2.5</sub> were  
139 determined by MARGA. For details on these instruments, please refer to Ding et al.  
140 (2016). The following section will focus on the measurement of HONO.

141 The WD/IC instrument for the HONO measurement used in our study was a Monitor  
142 for AeRosols and Gases in ambient Air for ambient air (Metrohm, Switzerland,  
143 MARGA) (Xie et al., 2015). The sampling system of the MARGA instrument  
144 comprised two parts: a wet rotating denuder for gases and a steam jet aerosol collector  
145 (SJAC) for aerosols, which worked at an air flow rate of 1 m<sup>3</sup> h<sup>-1</sup>. The trace gases,  
146 including SO<sub>2</sub>, NH<sub>3</sub>, HONO, HCl, and HNO<sub>3</sub>, were absorbed by the H<sub>2</sub>O<sub>2</sub> denuder  
147 solution with a concentration of 1mM. Subsequently, the ambient particles were  
148 collected in the SJAC. Hourly samples were collected in syringes, and analyzed with a  
149 Metrohm cation and anion chromatograph using an internal standard (LiBr). In our  
150 experiments, the flow rate of the absorption solution was 25 ml/hour.

151 As the intercomparison technology, HONO was also observed by a LOPAP (QUMA,  
152 Germany). The ambient air was sampled in two similar temperature-controlled

153 stripping coils in series using a mixture reagent of 100 g sulfanilamide and 1 L HCl  
154 (37% volume fraction) in 9 L pure water. In the first stripping coil, almost all of the  
155 HONO and a fraction of the interfering substances were absorbed in the solution named  
156 R1. In the second stripping coil, the remaining HONO and most of the interfering  
157 species were absorbed in the solution named R2. After adding 0.8 g N-  
158 naphthylethylenediamine-dihydrochloride reagent in 9 L pure water to both coils, a  
159 colored azo dye was formed in the solutions of R1 and R2, which were then separately  
160 detected via long-path absorption in special Teflon tubing. The interference-free  
161 HONO signal was the difference between the signals in the two channels. The method  
162 was believed to be an interference-free method for HONO measurement.

### 163 **3. Results and discussion**

#### 164 **3.1 Performance of MARGA for measuring atmospheric HONO**

165 During the observation period, the HONO concentration measured by LOPAP  
166 ( $\text{HONO}_{\text{lopap}}$ ) varied from 0.01 to 4.8 ppbv with an average value of  $1.1 \pm 0.77$  ppbv, and  
167 the HONO concentration measured by the MARGA instrument ( $\text{HONO}_{\text{marga}}$ ) was 0.01-  
168 9.6 ppbv, with an average value of  $1.52 \pm 1.21$  ppbv. The comparison between  
169  $\text{HONO}_{\text{lopap}}$  and  $\text{HONO}_{\text{marga}}$  values is shown in Figure 1. The ratio of  $\text{HONO}_{\text{marga}}$  to  
170  $\text{HONO}_{\text{lopap}}$  varied from 0.25 to 5, but  $\text{HONO}_{\text{marga}}$  was higher than  $\text{HONO}_{\text{lopap}}$  during  
171 most of the observation period (>70%). The diurnal variations in the HONO  
172 concentration in Figure 1b showed that  $\text{HONO}_{\text{marga}}$  was higher at night, specifically in  
173 the morning. This diurnal variations in  $\text{HONO}_{\text{marga}} / \text{HONO}_{\text{lopap}}$  were different from  
174 those reported in the study conducted by Muller et al. (1999), in which the  
175 overestimation of HONO by WD/IC was higher during the daytime. Meanwhile, the  
176 correlation between the HONO concentrations measured by WD/IC and other measured  
177 HONO concentrations varied in different studies. In our study, the slope of  $\text{HONO}_{\text{lopap}}$   
178 to  $\text{HONO}_{\text{marga}}$  was approximately 0.57, with a correlation coefficient  $r^2=0.3$ . Combined  
179 with the limited comparison study on HONO concentrations measured by a WD/IC  
180 instrument and LOPAP (Lu et al., 2010; Ramsay et al., 2018), the slope at the four sites

181 varied from 0.32 to 0.87. The large variation may indicate that the performance of  
182 WD/IC in the measurement of HONO is environmental dependent.

183 Here, the relationship between the measurement deviations and atmospheric  
184 compositions, including aerosols and major trace gases, during the observation was  
185 further analyzed, as shown in Figure 2. As the major precursor of HONO, the  
186 heterogeneous reaction of NO<sub>2</sub> on the sampling tube or aerosol may introduce the  
187 artificial HONO (Kleffmann et al., 2006; Gutzwiller et al., 2002; Liu et al., 2014; Xu et  
188 al., 2015). In our study, the results showed that the correlation between the deviations  
189 of HONO<sub>marga</sub> with regards to NO<sub>2</sub> and PM<sub>2.5</sub> is weak, thereby indicating that the  
190 hydrolysis of NO<sub>2</sub> on the tube surface or in PM<sub>2.5</sub> is not the major contributor resulting  
191 in the measurement deviation of HONO. However, the measurement deviation was  
192 notably affected by the ambient SO<sub>2</sub> (Figure 2c) and NH<sub>3</sub> (Figure 2d). Compared to  
193 HONO<sub>lopap</sub>, HONO<sub>marga</sub> was significantly higher at a high concentration of SO<sub>2</sub> and had  
194 the opposite trend at a high concentration of ammonia. A reasonable extrapolation was  
195 that SO<sub>2</sub> and NH<sub>3</sub>, as the main acid gas and alkaline gas in the atmosphere, were  
196 absorbed by the denuder solution in the process of sampling HONO. This process will  
197 impact the pH of the denuder solution and further change the absorption efficiency of  
198 HONO (Zellweger et al., 1999). In a real atmosphere, ambient SO<sub>2</sub> will be rapidly  
199 oxidized to sulfuric acid by H<sub>2</sub>O<sub>2</sub> in the denuder solution (Kunen et al., 1983), thereby  
200 lowering the pH. Similar to SO<sub>2</sub>, ammonia in the atmosphere is hydrolyzed to NH<sub>4</sub><sup>+</sup>  
201 and OH<sup>-</sup>, which increases the pH of the denuder solution. The variation in the pH of the  
202 denuder solution caused by atmospheric composition, specifically the condition of a  
203 high SO<sub>2</sub> concentration, will ultimately affect the absorption efficiency of HONO by  
204 the denuder.

### 205 **3.2 The influence of the denuder pH on HONO measurement by MARGA**

206 According to previous studies by Zellweger et al. (1999), the absorption efficiency of  
207 the denuder for HONO is mainly affected by the pH of the denuder solution, the flow  
208 rate of the absorbing liquid, the gas flow rate and the effective Henry coefficient of

209 HONO, as shown by formulas 1 and 2.

$$210 \quad \varepsilon = \frac{f_a}{f_g/H_{eff} + f_a} \quad (Eq.1)$$

$$211 \quad H_{eff} = H \left(1 + \frac{K_a}{H^+}\right) \quad (Eq.2)$$

212 where H is the Henry constant of HONO,  $H_{eff}$  is the effective Henry constant,  $K_a$  is the  
213 dissociation constant, and  $f_a$  and  $f_g$  are the flow rates ( $\text{ml min}^{-1}$ ) of the aqueous and  
214 gaseous phase, respectively.

215 The absorption efficiency of the MARGA instrument for HONO as calculated  
216 according to *Eq.1* and *Eq.2* is shown in Figure 3a. The absorption efficiency was  
217 sensitive to the pH of the denuder solution. Therefore, estimating the pH of the denuder  
218 solution was the first step and the key issue to evaluate the measurement deviation of  
219 HONO by WD/IC.

220 Here, we attempted to use the ion concentration of the denuder solution ( $\text{SO}_4^{2-}$ ,  $\text{NO}_3^-$ ,  
221  $\text{NO}_2^-$ ,  $\text{Cl}^-$ ,  $\text{Mg}_2^+$ ,  $\text{Ca}_2^+$ ,  $\text{NH}_4^+$ ,  $\text{Na}^+$ , and  $\text{K}^+$ ) measured by MARGA to inversely derive  
222 the pH of the denuder solution. The calculation of the pH was conducted with Curtipot,  
223 which is a simple software program that provides a fast pH calculation of any aqueous  
224 solution of acids, bases and salts, including buffers, zwitterionic amino acids, from  
225 single components to complex mixtures ([http://www.iq.usp.br/gutz/Curtipot\\_.html](http://www.iq.usp.br/gutz/Curtipot_.html)).  
226 As input of the model,  $\text{SO}_4^{2-}$ ,  $\text{NO}_3^-$ ,  $\text{NO}_2^-$ , and  $\text{NH}_4^+$  ions, which accounted for more  
227 than 98% of the total ions, were used. To verify the reliability of the calculation, a pH  
228 detector (Metrohm, 826 PH) was used to measure the pH of the denuder solution, which  
229 was collected in a clean glass bottle when the denuder solution was injected into the IC  
230 instrument. During the test, 13 samples were collected, and the pH results are shown in  
231 Figure 3b. When the pH value was lower than 5.6, the calculated pH ( $\text{pH}_a$ ) was close  
232 to the measured value ( $\text{pH}_c$ ), but when the value was higher than 7,  $\text{pH}_a$  was notably  
233 higher than  $\text{pH}_c$ . These results should be attributed to the buffering effect of carbonic  
234 acid in the denuder solution, which was exposed to the atmosphere. When the  
235 equilibrium between the  $\text{CO}_2$  and the carbonic acid in the denuder solution was reached,  
236 a carbonic acid buffer solution with a pH of 5.6 formed in the denuder solution with a

237 dissolved CO<sub>2</sub> concentration of 1.24\*10<sup>-5</sup> M (Seinfeld and Pandis, 2016;Stieger et al.,  
238 2018). Additionally, when the NH<sub>4</sub><sup>+</sup> concentration was higher than the total anion  
239 concentration in the denuder solution (SO<sub>4</sub><sup>2-</sup>, NO<sub>3</sub><sup>-</sup>, NO<sub>2</sub><sup>-</sup>, and Cl<sup>-</sup>), more CO<sub>2</sub> would be  
240 dissolved in the denuder solution, and the excess dissolved CO<sub>2</sub> could be equal to the  
241 excess NH<sub>4</sub><sup>+</sup>. After including the buffering solution of carbonic acid and excess CO<sub>2</sub>,  
242 the calculation of the pH values denoted as pH<sub>b</sub>, and pH<sub>b</sub> was in good agreement  
243 with the actual measurement results (pH<sub>c</sub>), which confirmed the feasibility of Curtipot  
244 to calculate the pH of the denuder solution. Therefore, the pH of the denuder solution  
245 during the observation period was calculated by the above method.

246 Under ideal conditions, the pH of the denuder absorption solution in MARGA (1mM  
247 H<sub>2</sub>O<sub>2</sub>) was approximately 6.97, and the absorption efficiency of MARGA for HONO  
248 should be 98% or higher under clear conditions. However, during the observation  
249 period, the calculated pH of the denuder solution varied from 4 to 7 due to the ambient  
250 SO<sub>2</sub> and NH<sub>3</sub> (Figure 4). Therefore, HONO<sub>marga</sub> was underestimated due to the low  
251 absorption efficiency caused by the low pH. In other words, the HONO<sub>marga</sub>/HONO<sub>lopap</sub>  
252 ratio will increase with decreasing pH. Assuming that the measurement deviation of  
253 HONO<sub>marga</sub> was only impacted by the collection efficiency, the HONO<sub>lopap</sub>/HONO<sub>marga</sub>  
254 ratio should be 1/ε (or HONO<sub>marga</sub>/HONO<sub>lopap</sub>=ε). Under this condition, the  
255 measurement deviation of HONO<sub>marga</sub> could be easily corrected according to the  
256 relationship between the HONO absorption efficiency and the calculated pH. However,  
257 most of the observed HONO<sub>lopap</sub>/HONO<sub>marga</sub> ratios were lower than 1/ε (Figure 4), thus  
258 indicating that HONO<sub>marga</sub> had still been overestimated even when the deviation of  
259 HONO caused by the variation in the denuder pH was corrected.

### 260 3.3 The artifact HONO due to NO<sub>2</sub> oxidizing SO<sub>2</sub>

261 To further analyze the MARGA measurement deviation of HONO, we first eliminated  
262 the influence of the denuder absorption efficiency on the measurement deviation  
263 according to the below correction formula.

$$264 \text{MARGA}_{\text{int.}} = \text{HONO}_{\text{Marga}} - \text{HONO}_{\text{LOPAP}} * \epsilon(\text{PH}) \quad (\text{Eq.3})$$

265 where  $MARGA_{int.}$  is the additional HONO produced during the sampling process.

266 In previous studies, the interference of HONO in the denuder solution mainly came  
267 from the  $NO_2$  hydrolysis reaction and the reaction between  $NO_2$  and  $SO_2$  (Febo et al.,  
268 1993; Spindler et al., 2003). Therefore, a correlation analysis of  $MARGA_{int.}$  with  $NO_2$   
269 and  $NO_2 \cdot SO_2$  was conducted. In the study by Spindler et al. (2003), approximately  
270 0.058% of  $NO_2$  was hydrolyzed to HONO, and this reaction contributed little to the  
271 artificial HONO in the denuder solution. In this study, we also found that approximately  
272 0.060% of  $NO_2$  was hydrolyzed to HONO at a low pH (<4.5) when the level of artifact  
273  $NO_2^-$  from the reaction between  $NO_2$  and  $SO_2$  was low (this part is discussed in the  
274 below section). Therefore, the hydrolysis of  $NO_2$  in the denuder solution minimally  
275 contributed to  $MARGA_{int.}$  However, the oxidation of  $SO_2$  with  $NO_2$  may have  
276 contributed to  $MARGA_{int.}$  in the basic or slightly acidic denuder solution (Jongejan et  
277 al., 1997; Spindler et al., 2003; Xue et al., 2019). In this study, the correlation between  
278  $MARGA_{int.}$  and  $SO_2 \cdot NO_2$  is shown in Figure 5(b). Compared to the study by Spindler  
279 et al. (2003), where the correlation with  $SO_2 \cdot NO_2$  was linear in an alkaline solution,  
280 the relationship between  $MARGA_{int.}$  and  $SO_2 \cdot NO_2$  was dependent on the pH of the  
281 denuder solution. The generation rate of HONO by  $SO_2 \cdot NO_2$  was low when the pH  
282 was <5, but would significantly increase with the pH. This discrepancy with the study  
283 by Spindler et al. (2003) should be due to the  $H_2O_2$  in the denuder solution.

284 Recently, Cheng et al. (2016) provided a detailed description of complete  $SO_2$  oxidation  
285 by  $H_2O_2$  and  $NO_2$  in the atmosphere. Due to the presence of  $H_2O_2$  in the denuder  
286 solution, a similar oxidation process of  $SO_2$  will also occur in the denuder solution.  
287 First, ambient  $SO_2$  undergoes a hydrolysis reaction when it is absorbed by the denuder  
288 solution. The reaction is shown in R1, and the fraction of the three components ( $\alpha H_2SO_3$ ,  
289  $\alpha HSO_3^-$ , and  $\alpha SO_3^{2-}$ ) is affected by the denuder pH (Figure 7a). After that,  $HSO_3^-$  and  
290  $SO_3^{2-}$  are simultaneously oxidized by  $H_2O_2$  and  $NO_2$  (Seinfeld and Pandis, 2016).

295 Here, the reaction ratios of  $\text{SO}_2$  oxidized by  $\text{H}_2\text{O}_2$  ( $P_{\text{H}_2\text{O}_2^* \text{S}}$ ) and  $\text{NO}_2$  ( $P_{\text{NO}_2^* \text{S}}$ ) in the  
296 denuder solution are shown in Figure 6b. The concentration of  $\text{H}_2\text{O}_2$  ( $[\text{H}_2\text{O}_2(\text{aq})]$ ) is  
297 1mM, the concentration of ambient  $\text{NO}_2$  ( $[\text{NO}_2]$ ) and  $\text{SO}_2$  ( $[\text{SO}_2]$ ) was assume as 1 ppbv,  
298 respectively. Because of the low solubility of  $\text{NO}_2$ , the aqueous  $\text{NO}_2$  [ $\text{NO}_2(\text{aq})$ ] in the  
299 denuder solution is balanced with  $[\text{NO}_2]$  in Henry's law.

300 
$$[\text{NO}_2(\text{aq})] = [\text{NO}_2] * H_{\text{NO}_2} \quad (\text{Eq. 4})$$

301 However, almost all the  $\text{SO}_2$  was absorbed by the denuder solution of 1mM  $\text{H}_2\text{O}_2$   
302 (Rosman et al., 2001; Rumsey et al., 2014), therefore the  $[\text{SO}_2(\text{aq})]$  was determined by  
303  $[\text{SO}_2]$ , sampling flow and the flow of denuder liquid, thereby the  $[\text{HSO}_3^-(\text{aq})]$  and  $[\text{SO}_3^{2-}$   
304  $(\text{aq})]$  was determined by the pH and  $[\text{SO}_2(\text{aq})]$  at the beginning of the oxidation reaction  
305 by  $\text{H}_2\text{O}_2$  or  $\text{NO}_2$ .

306 
$$[\text{SO}_2(\text{aq})] = [\text{SO}_2] * fg/fa \quad (\text{Eq. 5})$$

307 
$$[\text{HSO}_3^-(\text{aq})] = [\text{SO}_2(\text{aq})] * \alpha_{\text{HSO}_3^-} \quad (\text{Eq. 6})$$

308 
$$[\text{SO}_3^{2-}(\text{aq})] = [\text{SO}_2(\text{aq})] * \alpha_{\text{SO}_3^{2-}} \quad (\text{Eq. 7})$$

309 The result is as shown in Figure 6. In the case of a lower pH, more  $\text{HSO}_3^-$  would be  
310 present in the solution. At this point, the oxidation of  $\text{SO}_2$  in the solution was mainly  
311 due to  $\text{H}_2\text{O}_2$ . With the increase in pH, the  $\text{HSO}_3^-$  concentration of the solution decreased,  
312 while the  $\text{SO}_3^{2-}$  concentration of the solution increased. The role of  $\text{NO}_2$  in the oxidation  
313 of  $\text{SO}_2$  gradually increased, and the ratio of  $P_{\text{NO}_2^* \text{S}}/P_{\text{S(IV)}}$  rose rapidly and remained at  
314 nearly 100% at a pH of 8, which indicated that almost all  $\text{SO}_2$  was oxidized by  $\text{NO}_2$  at  
315 this point.

316 Now, the question was whether the observed MARGA<sub>int.</sub> could be explained by the  
317 reaction between  $\text{SO}_2$  and  $\text{NO}_2$ . This question could be answered by comparing  
318  $\text{MARGA}_{\text{int.}}/(\text{SO}_2^* \text{NO}_2)$  and  $P_{\text{NO}_2^* \text{S}}/P_{\text{S(IV)}}$  because  $\text{NO}_2^-$  was formed in the denuder  
319 solution only when  $\text{SO}_2$  was oxidized by  $\text{NO}_2$ . Here, the correlation between the

320 MARGA<sub>int.</sub> production rate and SO<sub>2</sub>, NO<sub>2</sub> and the denuder pH is also shown in Figure  
321 7(a). MARGA<sub>int.</sub>/(SO<sub>2</sub>\*NO<sub>2</sub>) was in good agreement with the theoretically calculated  
322 P<sub>NO<sub>2</sub>\*S</sub>/P<sub>S(IV)</sub>, thereby confirming that the chemical reaction between SO<sub>2</sub> and NO<sub>2</sub> did  
323 lead to the additional HONO production, which then resulted in the MARGA  
324 overestimations of the HONO measurements. Additionally, under the condition of 1  
325 ppb NO<sub>2</sub> concentration, as well as a range of the denuder pH of 4 to 7, only  
326 approximately 10% of the SO<sub>2</sub> was oxidized by NO<sub>2</sub>, which indicated that MARGA<sub>int.</sub>  
327 was low. However, during our observation, there was up to 50 ppbv NO<sub>2</sub>. Under these  
328 conditions, the oxidation of SO<sub>2</sub> by NO<sub>2</sub> was greatly elevated. As shown in Figure 7b,  
329 the high NO<sub>2</sub> concentrations of the ambient air (circle dots) were consistent with the  
330 P<sub>NO<sub>2</sub>\*S</sub>/P<sub>S(IV)</sub> values calculated from ambient air NO<sub>2</sub> concentrations (black squares),  
331 which also confirmed the results.

332 In the reaction of SO<sub>2</sub> and NO<sub>2</sub>, pH is the limiting factor. In the low pH, the dissolved  
333 SO<sub>2</sub> in denuder solution major presented as the HSO<sub>3</sub><sup>-</sup>, which will be rapidly oxidized by  
334 H<sub>2</sub>O<sub>2</sub>. In a real atmosphere, NH<sub>3</sub> is the major basic species to maintain the high pH of  
335 denuder solution. Therefore, NH<sub>3</sub> is the key composition influencing MARGA<sub>int.</sub>.  
336 Figure 8 shows the scenario of calculating MARGA<sub>int.</sub> from the reaction between SO<sub>2</sub>  
337 and NO<sub>2</sub> with ambient NH<sub>3</sub> concentrations of 5 ppbv and 20 ppbv. As shown in the  
338 figure, in the case of the 5 ppbv NH<sub>3</sub> concentration, the denuder pH would rapidly  
339 decrease with increasing SO<sub>2</sub> concentration. At this point, the formation process of  
340 MARGA<sub>int.</sub> from SO<sub>2</sub> and NO<sub>2</sub> was limited. However, for a high NH<sub>3</sub> concentration,  
341 the pH of the denuder solution would slowly decrease due to neutralization of NH<sub>3</sub> by  
342 sulfuric acid. A concentration of 1.2 ppb of artifact HONO could be produced with a  
343 NO<sub>2</sub> concentration of 40 ppbv and a SO<sub>2</sub> concentration of 4 ppbv. MARGA<sub>int.</sub> would  
344 be greatly improved at a high concentration of NH<sub>3</sub>.

345 In east China, NH<sub>3</sub> concentration is in general high, and keep increasing 30% from 2008  
346 to 2016 in NCP (Liu et al., 2018). Especially in summer, NH<sub>3</sub> concentration can be up  
347 to 30 ppb (Meng et al., 2018). In contrast, the SO<sub>2</sub> concentration is gradually decreasing  
348 due to the emission reduction from 2008 to 2016 (around 60%), with the concentration  
349 lower than 5 ppb frequency observed. In such case, the pH of the denuder solution in

350 the WD/IC instrument will be further enhanced, which will in turn further aggravate  
351 the deviation of the HONO measurement.

### 352 **3.4 The correction for the HONO measurement interference**

353 According to the above results, the deviation of MARGA for the HONO measurement  
354 could be caused by two factors: one is the low sampling efficiency of the denuder  
355 solution at low pH, and the other is the external  $\text{NO}_2^-$  that is produced by the reaction  
356 between  $\text{SO}_2$  and  $\text{NO}_2$  at high pH. In this study, we attempted to correct the  
357 measurement deviation of HONO accordingly. The correction formula is as follows:

$$358 \quad \text{MARGA\_correct} = (\text{HONO}_{\text{marga}} - \text{SO}_2 * \text{NO}_2 * P_{(\text{pH})} - \text{NO}_2 * 0.0056) / \varepsilon_{(\text{pH})} \quad (\text{Eq.8})$$

359 The calculation results are shown in the Figure 9 (a). After correction, there was a  
360 significant improvement in the measured HONO by MARGA, and the  $r^2$  value between  
361  $\text{HONO}_{\text{marga}}$  and  $\text{HONO}_{\text{Iopap}}$  increased from 0.28 to 0.61, specifically in the high  
362 concentration range of HONO. However, when the concentration of HONO was low,  
363 the degree of improvement was limited. To find the reason for the uncertainty of  
364 correction, the residual analysis was made. The residual was the difference between  
365  $\text{MARGA}_{\text{int}}$  and calculated interference from  $\text{SO}_2 * \text{NO}_2 * P_{(\text{pH})} - \text{NO}_2 * 0.0056$ . The  
366 dependency of residual/ $\text{NO}_2$  on RH is similar with that of ambient HONO/ $\text{NO}_2$  on RH  
367 which was observed in many other studies (Li et al., 2012; Yu et al., 2009), and indicate  
368 the  $\text{NO}_2$  heterogeneous reaction or the reaction of  $\text{SO}_2$  and  $\text{NO}_2$  in the sampling tube  
369 may be another factors impacting the HONO interference (Su et al., 2008a).

370 Moreover, the uncertainty of correction  $\text{HONO}_{\text{marga}}$  may have been attributed to another  
371 two reasons. One is the uncertainty of the pH of the denuder solution. The pH of the  
372 denuder solution was calculated according to the ions formed from the absorbed gas in  
373 the denuder solution with a residence time of 1 hour, whereas the oxidation of  $\text{SO}_2$   
374 occurred in real time when the pH of the denuder solution also varied. Additionally, the  
375 low concentration ions ( $<5 * 10^{-5}$  M) in the denuder solution will induce uncertainties in  
376 calculating the pH. Another reason is the uptake coefficient of the denuder solution.  
377  $\text{NO}_2$  (g) is weakly soluble in pure water with a Henry's law constant (H) of  $\sim 0.01$  M

378  $\text{atm}^{-1}$ , which was used in this study. However, previous studies have shown that the  
379 anions in the liquid greatly enhance the  $\text{NO}_2$  (g) uptake by two or three orders of  
380 magnitude (Li et al., 2018). This process may influence the calculation of the dissolved  
381  $\text{NO}_2$  content and its hydrolysis. The accuracy of the uptake coefficient was difficult to  
382 determine, which might be one of the reasons for the underestimation of  $\text{MARGA}_{\text{int}}$   
383 for the reaction between  $\text{SO}_2$  and  $\text{NO}_2$  at a high concentration of  $\text{NO}_2$  (Figure 7b).

384 In addition to the correction, an alternative way to use  $\text{HONO}_{\text{marga}}$  is to select the  
385 suitable conditions where the measurement interference is limited. In ambient air,  $\text{SO}_2$   
386 and  $\text{NH}_3$  are the key pollutants resulting in the HONO measurement deviation.  
387 According to our observations, under the clear condition of  $\text{SO}_2 \cdot \text{NO}_2$  lower than 150  
388  $\text{ppbv}^2$  (median value) and a  $\text{NH}_3$  content lower than 5 ppbv (median value), MARGA  
389 showed a much better performance for measuring the HONO concentration. The latter  
390 was also the possible reason for the suitable performance of WD/IC in measuring  
391 HONO concentrations in previous studies (Acker et al., 2004; Ramsay et al., 2018).

#### 392 **4. Conclusion**

393 We conducted a field campaign at the SORPES station in December 2015 to evaluate  
394 the performance of MARGA for measuring ambient HONO concentrations with the  
395 benchmark of LOPAP. Compared with  $\text{HONO}_{\text{lopap}}$ , a notable deviation in  $\text{HONO}_{\text{marga}}$   
396 was observed between -2 and 6 ppb, and the ratio of  $\text{HONO}_{\text{marga}}/\text{HONO}_{\text{lopap}}$  ranged from  
397 0.4 to 4. When the  $\text{SO}_2$  concentration in the atmosphere was high, a negative deviation  
398 occurred, and when the  $\text{NH}_3$  concentration was high, a positive deviation occurred.

399 Through further analysis of the pH of the denuder solution and the oxidation of  $\text{SO}_2$  in  
400 the denuder solution, the deviation of the measurement of HONO by MARGA is mainly  
401 due to two reasons. One is that an acidic-alkaline gas component in the atmosphere  
402 enters the denuder solution of the instrument, thereby causing the denuder pH to change,  
403 affecting the absorption efficiency of MARGA for HONO. Another reason is that  $\text{NO}_2$   
404 oxidizes the  $\text{SO}_2$  absorbed in the denuder solution, and the reaction is generally  
405 improved with a higher pH of the denuder solution in the presence of high

406 concentrations of NH<sub>3</sub> and NO<sub>2</sub>. The additional formation of HONO led to the MARGA  
407 measurement error of HONO.

408 Based on the understanding of the interference factors, we established a method to  
409 correct the HONO data measured by MARGA. Compared with LOPAP, the HONO  
410 measurement results were improved after the correction, but the improvement was  
411 limited at a low concentration of HONO. Moreover, under the clear conditions of low  
412 concentrations of SO<sub>2</sub>, NO<sub>2</sub>, and NH<sub>3</sub>, MARGA will have a better performance for the  
413 measurement of HONO.

### 573 **Data availability.**

574 Measurement data at SORPES, including aerosol data and relevant trace gases as well

575 as meteorological data, are available upon request from the corresponding author before  
576 the SORPES database is open to the public.

577 **Author contributions**

578 AD and WN designed the study and contributed to the editing of the paper. ZX,  
579 contributed to the measurements, data analysis, and the first draft of this paper., YL  
580 contributed to the data analysis. PS, XC contributed in observation at SORPES and  
581 data analysis.

582 **Competing interests**

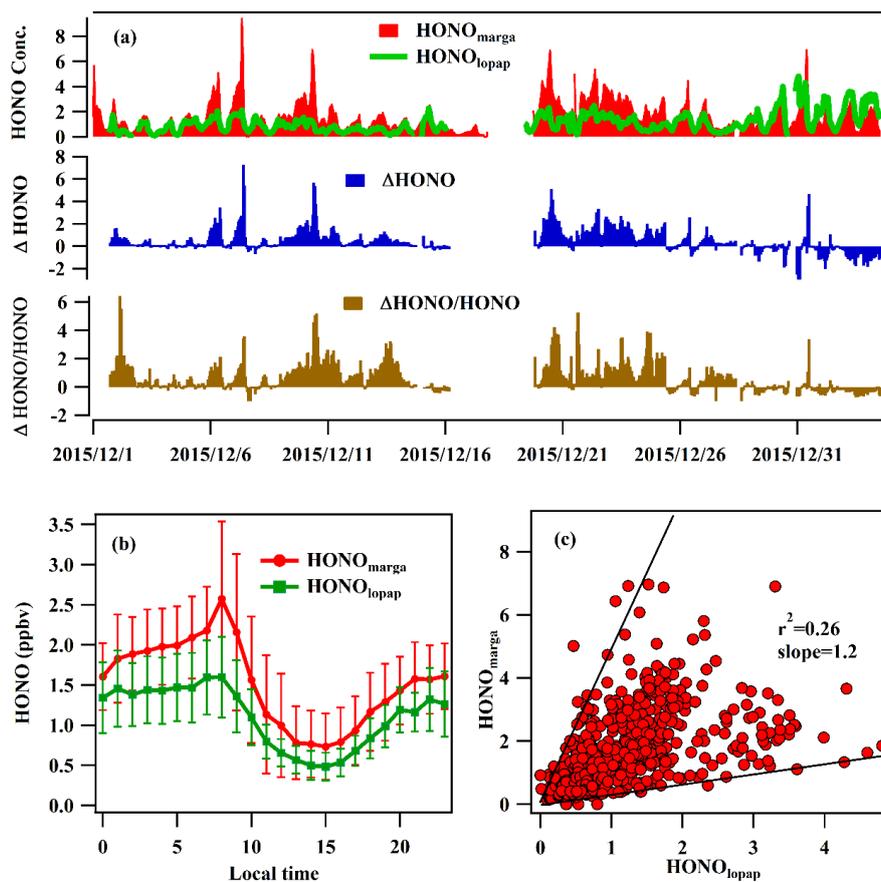

583 The authors declare that they have no conflict of interest

584 **Acknowledgments**

585 The research was supported by National Key Research & Development Program of  
586 China (2016YFC0200500), National Science Foundation of China (41605098) and  
587 Jiangsu Provincial Science Fund (BK20160620), this study was also supported by the  
588 other National Science Foundation of China (91644218)  
589

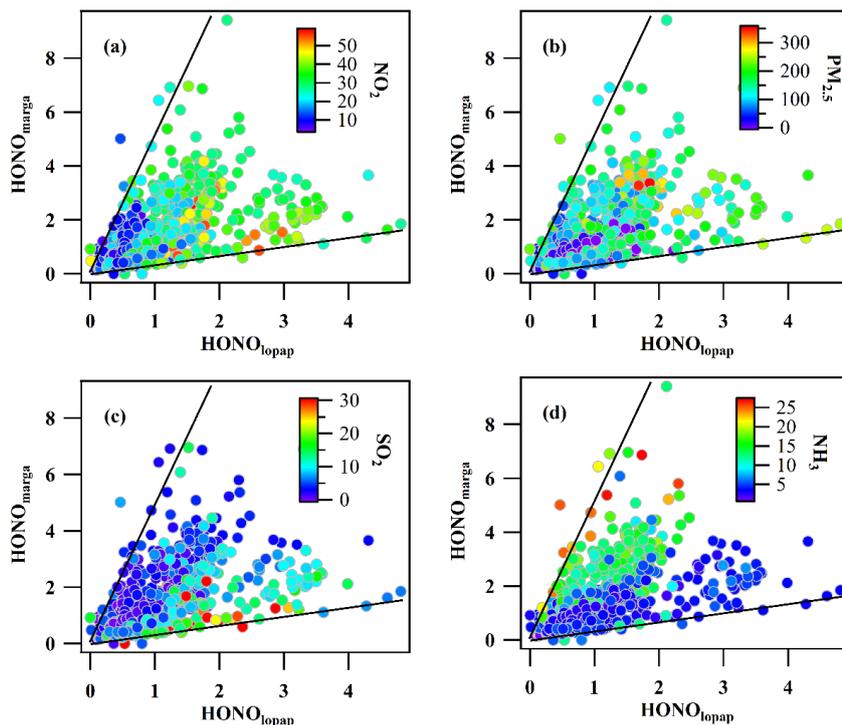

590 **Figure 1-10**

591

592 Figure 1. The time series of HONO concentrations measured by the LOPAP ( $\text{HONO}_{\text{lopap}}$ )  
593 and MARGA instruments ( $\text{HONO}_{\text{marga}}$ ), the deviation of  $\text{HONO}_{\text{marga}}$  including  $\Delta\text{HONO}$   
594 ( $\text{HONO}_{\text{marga}} - \text{HONO}_{\text{lopap}}$ ) and  $\Delta\text{HONO}/\text{HONO}$ , with regards to the benchmark of  
595 HONO (a), the average diurnal variations (b) and their scatter plot during the  
596 observation period (c).
