8 Abstract

9 Among the various measurement approaches to quantify light absorption coefficient (B_{abs}), filter-
10 based absorption photometers are dominant in monitoring networks around the globe. Numerous
11 correction algorithms have been introduced to minimize the artifacts due to the presence of the
12 filter in these instruments. However, from our recent studies conducted during the Fire Influence
13 on Regional and Global Environments Experiment (FIREX) laboratory campaign, corrected filter-
14 based B_{abs} remains biased high by roughly a factor of 2.5 when compared to a reference value
15 using a photoacoustic instrument for biomass burning emissions. Similar over-estimations of B_{abs}
16 from filter-based instruments exist when implementing the algorithms on six months of ambient
17 data from the Department of Energy (DOE) Atmospheric Radiation Measurement (ARM)
18 Southern Great Plains (SGP) user facility from 2013 (factor of roughly 3). In both datasets, we
19 observed an apparent dependency on single scattering albedo (SSA) and absorption Ångström
20 exponent (AAE) in the agreement between B_{abs} based on existing correction factors and the
21 reference B_{abs} . Consequently, we developed a new correction approach that is applicable to any
22 filter-based absorption photometer that includes light transmission from the filter-based instrument
23 as well as the derived AAE and SSA. For the FIREX and SGP datasets, our algorithm results in
24 good agreement between all corrected filter-based B_{abs} values from different filter-based
25 instruments and the reference (slopes ≈ 1 and $R^2 \approx 0.98$ for biomass burning aerosols and slopes
26 ≈ 1.05 and $R^2 \approx 0.65$ for ambient aerosols). Moreover, for both the corrected B_{abs} and the derived
27 optical properties (SSA and AAE), our new algorithms work better or at least as well as the two
28 common PSAP-based correction algorithms. The uncertainty of the new correction algorithm is
29 estimated to be $\sim 10\%$, considering the measurement uncertainties of the operated instruments.
30 Therefore, our correction algorithm is applicable to any filter-based absorption photometer and
31 has the potential to “standardize” reported results across any filter-based instrument.

32 1. Introduction

33 Light-absorbing atmospheric aerosols directly affect the Earth’s energy budget by absorbing solar
34 radiation, leading to a warming effect when they are suspended in the atmosphere and to the
35 melting of snow and ice following deposition (Bond and Bergstrom, 2006; Boucher, 2015; Horvath,
36 1993). For decades, scientists have conducted field experiments around the globe to investigate
37 how absorbing aerosols influence the atmospheric radiative balance and interact with clouds (e.g.,
38 Andrews et al. (2011); Cappa et al. (2016); Lack et al. (2008b); Rajesh and Ramachandran (2018);
39 Schwarz et al. (2008)). These experiments may be performed at fixed stations (e.g., observation
40 sites maintained by the Department of Energy (DOE) Atmospheric Radiation Measurement (ARM)
41 program or the National Oceanic and Atmospheric Administration (NOAA) Global Monitoring

42 Division (GMD)) or on mobile platforms (e.g., car trailer, aircraft, and ship), typically involving
43 the measurements of aerosol chemical, physical, and optical properties. Crucial to the
44 quantification of the radiative forcing of absorbing aerosols are measurements of the absorption
45 coefficient (B_{abs}). For example, long-term monitoring of B_{abs} provides essential data to evaluate
46 chemistry-climate model simulations (e.g., Chen et al. (2019); Vignati et al. (2010)), while
47 intensive measurements of B_{abs} during short-term field campaigns allow for the investigation of
48 optical properties that govern features of aerosol forcing (e.g., McMeeking et al. (2014); Olson et
49 al. (2015)).

50 A variety of instruments have been used to measure B_{abs} , which generally classified into two large
51 categories: filter-based techniques and photoacoustic techniques (Lack et al., 2014; Moosmüller
52 et al., 2009). The major difference between the two categories of technique is that B_{abs} is measured
53 after the aerosols are deposited on the filter media in the filter-based instruments, while the aerosols
54 are characterized within an air stream in the photoacoustic instruments. Compared to the filter-
55 based instruments, the photoacoustic instruments have the advantage of avoiding potential artifacts
56 due to the contact of aerosols with filters; therefore, they are often used as the reference instruments
57 in inter-comparison studies of aerosol absorption (e.g., Arnott et al. (2005); Davies et al. (2019);
58 Jiang et al. (2018); Li et al. (2019); Schmid et al. (2006); Sheridan et al. (2005)).

59 Filter-based absorption photometers have been widely used at observational sites around the world
60 due to their ease of operation and relatively low cost. Numerous instruments can be classified as
61 filter-based absorption photometers including the Radiance Research Particle Soot Absorption
62 Photometer (PSAP), the NOAA Continuous Light Absorption Photometer (CLAP), the Brechtel
63 Manufacturing Tricolor Absorption Photometer (TAP), the Magee Scientific Aethalometer
64 (AETH), and the Thermo Scientific Multi-Angle Absorption Photometer (MAAP). Operationally,
65 all of these instruments are similar in that aerosols are deposited onto a filter and the reduction in
66 the transmission (Tr) of light by the particles (sometimes called attenuation (ATN)) is used to infer
67 B_{abs} . Where the instruments may differ is that some are multi-wavelength (multi- λ) instruments
68 (e.g., 3 λ -PSAP, CLAP, TAP, 7 λ -AETH models), while others are not (e.g., 1 λ -PSAP, other AETH
69 models, MAAP).

70 One challenge with filter-based absorption photometers is that biases can arise due to the presence
71 of the filter. For example, light scattering by particles loaded onto the filter or by the filter itself
72 may affect the transmission of light (e.g., (Arnott et al., 2005; Bond et al., 1999)); non-absorbing
73 material may result in absorption enhancement (e.g., (Cappa et al., 2008)); or organic vapors
74 adsorbed to the filter may itself absorb light (e.g., (Subramanian et al., 2007)). Consequently,
75 various correction algorithms exist to minimize these biases, but they are often specific only to
76 certain instruments. For example, some are applicable to the PSAP, CLAP, and TAP (e.g., (Bond
77 et al., 1999; Müller et al., 2014; Ogren, 2010; Virkkula, 2010; Virkkula et al., 2005)), while others
78 are applicable to the AETH (e.g., (Arnott et al., 2005; Collaud Coen et al., 2010; Drinovec et al.,
79 2017; Kirchstetter and Novakov, 2007; Schmid et al., 2006; Virkkula et al., 2007, 2015;
80 Weingartner et al., 2003)).

81 Although the equations associated with these existing correction algorithms are different, they
82 share some commonalities. For example, the filter-based absorption photometers are assessed
83 using laboratory (e.g., ammonium sulfate, fullerene soot) or ambient aerosols during experiments
84 which include reference measurements of B_{abs} . These reference measurements often include either
85 direct photoacoustic B_{abs} or inferred B_{abs} as the difference between the extinction coefficient (B_{ext})

86 and the scattering coefficient (B_{scat}). Correction equations are developed by comparing data
87 between the filter-based instrument and the reference instrument, where the equations often
88 contain one term that accounts for filter loading effects and another that accounts for multiple-
89 scattering effects. Consequently, the correction equations frequently incorporate both Tr and either
90 B_{scat} or the single-scattering albedo (SSA) to account for these effects. However, even when the
91 correction algorithms are applied, potential issues can remain such as:

- 92 1. Corrected filter-based B_{abs} may remain biased high relative to a reference value of B_{abs} (e.g.,
93 (Arnott et al., 2003; Davies et al., 2019; Lack et al., 2008a; Li et al., 2019; Müller et al., 2011a)).
- 94 2. Comparisons between the reference instrument and B_{abs} corrected by different algorithms can
95 yield variable agreement (e.g., (Collaud Coen et al., 2010; Davies et al., 2019; Saturno et al.,
96 2017)).
- 97 3. Corrected B_{abs} from different filter-based absorption photometers may not agree (e.g., (Davies
98 et al., 2019; Müller et al., 2011a)).
- 99 4. Derived products (such as absorption Ångström exponents (AAE)) may differ based on the
100 implemented correction algorithm (e.g., (Backman et al., 2014; Davies et al., 2019)).
- 101 5. The agreement between measurements of B_{abs} and estimates of B_{abs} by chemistry-climate
102 models may vary based on the implemented correction algorithm (e.g., (Alvarado et al., 2016)).

103 The first three issues in this list may arise due to differences in aerosol optical properties between
104 those used in deriving the correction equation and those associated with a given aerosol sample,
105 and these issues can propagate through to the fourth issue. The final issue is arguably most
106 important because evaluation of chemistry-climate models may be severely affected by the
107 differences between different correction algorithms, which may inhibit the modeling community
108 from providing accurate projections of future temperature and precipitation response.

109 In this work, we seek to address some of these issues. First, we evaluate the CLAP, TAP, and
110 PSAP using two common PSAP-based correction algorithms, namely Bond et al. (1999) as
111 updated by Ogren (2010) and Virkkula et al. (2005) as updated by Virkkula (2010). For brevity,
112 we refer to these corrections as “B1999” and “V2005” for Bond et al. (1999) and Virkkula et al.
113 (2005), respectively, incorporating their respective updates. In addition, we propose new
114 correction algorithms that are applicable to any filter-based absorption photometer (e.g., CLAP,
115 TAP, PSAP, and AETH) across multiple wavelengths by combining observed filter-based B_{abs}
116 with B_{scat} (e.g., from a co-located nephelometer (NEPH)) and reference B_{abs} (e.g., from a co-
117 located photoacoustic instrument). However, in reality (e.g., at long-term observatories), reference
118 values of B_{abs} are rare, and in some cases, complementary B_{scat} measurements may not exist;
119 consequently, we also provide methods to correct filter-based B_{abs} data in these scenarios. To our
120 knowledge, this is the first study to simultaneously evaluate B1999 and V2005 corrections on
121 PSAP “successors” (i.e., CLAP and TAP) and to present a correction algorithm that is broadly
122 applicable to any filter-based absorption photometer. Regarding the latter, even if our correction
123 algorithm has its own limitations, its use can nevertheless standardize the reporting of B_{abs} in long-
124 term datasets.

125 2. Methodology

126 We developed the general form for our correction algorithms using CLAP and TAP measurements
127 collected from biomass burning (65 fires in total) during the Fire Influence on Regional to Global
128 Environments Experiment (FIREX) laboratory campaign in 2016. By using biomass burning

129 emissions, we considered a dataset spanning a broader range of aerosol optical properties (SSA at
130 652 nm: 0.14-0.98; AAE: 1.25-4.73) than has traditionally been used in developing these
131 correction algorithms. We then conducted further evaluation and validation of the model using
132 ambient data, specifically using CLAP measurements from the DOE ARM Southern Great Plains
133 (SGP) user facility in Lamont, OK, USA (02/01/13 to 07/09/13). Our algorithms were then
134 extended to the AETH data from the FIREX laboratory campaign and the PSAP data collected at
135 the SGP site to verify the generalizability of the algorithms.

136 2.1. The FIREX campaign

137 2.1.1. Experimental setup

138 In October and November of 2016, we participated in the laboratory portion of the FIREX
139 campaign to investigate the wildfire smoke and their impact on the atmosphere. During the
140 campaign, over 100 burns took place at the U.S. Forest Service’s combustion facility at the Fire
141 Sciences Laboratory (FSL). The fuels burned in this study are representative of western US
142 ecosystems, such as spruce, fir, various pines, and “chaparral” biome (e.g., manzanita, chamise).
143 (See Koss et al. (2018) and Selimovic et al. (2018) for more details).

144 A typical burn lasted for 1-3 hours depending on the smoke sampling strategies (e.g., stack burns
145 versus room burns). During each burn, one or multiple “snapshots” of smoke (typical B_{abs} at 652
146 nm ranged from 100 to 1200 Mm^{-1}) were transferred from the combustion room at FSL into a
147 mixing chamber (210 L) through a long transfer duct (30 m in length, 8” in diameter). The smoke
148 was then diluted by filter air (~230 LPM) in the chamber. Once the concentration in the chamber
149 was stable (detected by the Photoacoustic Extinctionmeter (PAX) which was operated continuously
150 through all fires), the smoke was passed to a suite of instruments to obtain aerosol and gas phase
151 parameters. This chamber also served as an intermediate between the transfer duct and the
152 instrumentation to minimize potential biases that arose due to different sample flow rates and
153 sample locations of the instruments. A more detailed description of our experiments can be found
154 in Li et al. (2019).

155 2.1.2. Measurements of aerosol optical properties

156 During the campaign, five instruments provided measurements of B_{abs} (CLAP, NOAA GMD; TAP,
157 Brechtel Manufacturing Inc. (BMI); Aethalometer (Model AETH-31), Magee Scientific; and two
158 PAXs (Model PAX-870 and PAX-405), Droplet Measurement Technologies) and two instruments
159 provided measurements of B_{scat} (PAX-870 and PAX-405). The instruments included in the present
160 work are summarized in Table 1.

161 Both CLAP and TAP provide B_{abs} measurements of the particles deposited on a filter, similar to
162 PSAP. Different from PSAP, there are multiple filter spots (8 sample spots and 2 reference spots)
163 cycling of one filter in CLAP and TAP, enabling the instruments to run continuously through two
164 or three burns without changing filter. In the CLAP and TAP, sample illumination is provided by
165 LEDs operated at three wavelengths (467, 528, and 652 nm). Here, we apply both B1999 and
166 V2005 to CLAP and TAP data, similar to previous work (e.g., (Backman et al., 2014; Davies et
167 al., 2019)).

168 The key differences between the CLAP and TAP during the FIREX campaign include:

- 169 1. The spot change of the CLAP was manually performed when Tr reached approximately 0.5
170 (or ATN decreased to ~69), while the TAP advanced to a new spot automatically with a Tr
171 threshold set to be 0.5.
- 172 2. The spot area, flow rate, and LED-detected wavelengths differed slightly (Table 1).
- 173 3. The CLAP recorded B_{abs} every one minute, while the TAP recorded B_{abs} every ten seconds. To
174 enable the following analysis, we compute the 1-minute averages of TAP-derived parameters.
- 175 4. For the first portion of the campaign (the first 17 days of the 45-day campaign), Pallflex E70-
176 2075S filters were used in the CLAP while Azumi filters (model 371M, Azumi Filter Paper
177 Co., Japan) were used in the second portion of the campaign (due to a lack of availability of
178 the Pallflex filters). The TAP was equipped exclusively with the Azumi filters throughout the
179 campaign. We apply the filter correction recommended in Ogren et al. (2017) to the CLAP and
180 convert from Pallflex to Azumi filters.
- 181 5. BMI substantially re-engineered the CLAP in their development of the TAP.

182 These differences resulted in variable agreement between the CLAP and TAP during FIREX;
183 however, the two instruments did largely agree within experimental uncertainty (e.g., see Fig. S8
184 and Fig. S13 in Li et al. (2019)).

185 A PAX measures B_{abs} and B_{scat} simultaneously for suspended particles using a modulated diode
186 laser. We use these photoacoustic absorption measurements as the reference to evaluate the filter-
187 based B_{abs} and develop our correction algorithms. To enable the evaluation of CLAP and TAP
188 which operate at different wavelengths than the PAXs, we interpolate the measurements of B_{abs}
189 and B_{scat} to the wavelengths of 467, 528, and 652 nm using the values of AAE and scattering
190 Ångström exponents (SAE), similar to Backman et al. (2014) and Virkkula et al. (2005).
191 Theoretically, AAE and SAE fit absorption and scattering as power law functions of wavelength
192 (Bergstrom et al., 2007).

193 Due to the numerous correction algorithms for the Aethalometer (e.g. (Arnott et al., 2005; Collaud
194 Coen et al., 2010; Kirchstetter and Novakov, 2007; Saturno et al., 2017; Schmid et al., 2006;
195 Virkkula et al., 2007; Weingartner et al., 2003)), we do not evaluate these in the present work to
196 limit the scope. In fact, the majority of our focus is the B1999 and V2005 corrections to TAP and
197 CLAP. However, we still test the performance of the new algorithms on the AETH to explore its
198 applicability to that instrument.

199 2.2. Measurements of aerosol optical properties at the SGP observatory

200 The ambient data used in this manuscript are the ground-based aerosol data measured at the SGP
201 observatory from 02/01/13 to 07/09/13 (archived at <https://www.archive.arm.gov/discovery/>). For
202 evaluation purposes, we randomly select a range of dates during which the observations are valid
203 (without incorrect, suspect, and missing data) and the PASS is operated after laser (532 nm)
204 upgrade.

205 At the site, an impactor was used to switch the sampling between two cutoffs (particle diameter
206 $<10 \mu\text{m}$ (PM10) in the first 30 minutes of each hour and $<1 \mu\text{m}$ (PM1) in the latter 30 minutes of
207 each hour). The aerosols exiting from the impactor were dried to RH less than 40% and passed to
208 a CLAP, a PSAP, and two NEPHs. Moreover, a three-wavelength photoacoustic soot spectrometer
209 (PASS-3) was operated at the site and measured B_{abs} and B_{scat} of the aerosols, but these aerosols
210 did not pass through the impactor (e.g., characterizing total suspended particles (TSP)). Typical
211 B_{abs} and B_{scat} reported at the site ranged from 0 to 10 Mm^{-1} and 0 to 50 Mm^{-1} at 550 nm, respectively

212 (e.g., (Sherman et al., 2015)). Although the site is rural (clean background air), long-term transport
213 aerosols (such as mineral dust, absorbing organic aerosols, and secondary organic aerosols (SOA))
214 may affect the local aerosol properties (Andrews et al., 2019).

215 We preprocess the SGP data in three steps. First, due to the systematic difference of aerosol sizes
216 between PASS-derived and filter-based absorption, we only include the PM10 observations,
217 inherently assuming that any differences in the optical properties of PM10 and TSP are negligible.
218 Then, we smooth the 1-second data into 10-minute averages. Thirdly, we estimate the detection
219 limits at each of the three wavelengths in the PASS-3 using the data measured during the
220 “background zero” periods (Allan, 1966) and discard the observations which are below the
221 detection limits. With a 10-min-averaging-time, the detection limits (3σ) for the PASS-3 are 0.78
222 Mm^{-1} (405 nm), 2.01 Mm^{-1} (532 nm), and 0.30 Mm^{-1} (781 nm). For the filter-based instruments,
223 the detection limits are based on previous studies (See Table 1). Moreover, we only retain the
224 observations that satisfy $B_{\text{abs}}(405 \text{ nm}) > B_{\text{abs}}(532 \text{ nm}) > B_{\text{abs}}(781 \text{ nm})$ (or $\text{AAE} > 0$), similar to
225 Fischer and Smith (2018). As with the PAX data from the laboratory, we adjust the PASS-derived
226 B_{abs} to 467, 528, and 652 nm using the inferred AAE values for each 10-minute average.

Table 1 Summary of specifications for instruments relevant to this work.

Instrument	Flow rate (LPM)	Spot area (cm ²)	Type of filter	Measured parameters	Response time	Measurement uncertainty	Detection limit (3 σ , Mm ⁻¹)
PAX-870	1.0	-	-	B _{abs} and B _{scat} (870 nm)	1s	~11% (B _{abs}) ~17% (B _{scat}) (Nakayama et al., 2015)	0.47 (B _{abs}) 0.66 (B _{scat}) ^a
PAX-405	1.0	-	-	B _{abs} and B _{scat} (405 nm)	1s	4% (B _{abs}) 7% (B _{scat}) (Nakayama et al., 2015)	0.27 (B _{abs}) 0.60 (B _{scat}) ^a
PASS-3 ^b	1.0	-	-	B _{abs} and B _{scat} (405, 532, and 781 nm)	1s	4 %, 8 %, and 11 % (B _{abs}) (Nakayama et al., 2015)	0.78 (405 nm) 2.01 (532 nm) 0.30 (781 nm) ^a
NEPH ^b	7.5	-	-	B _{scat} (450, 550, and 700 nm)	1s	10% (Anderson et al., 1996)	0.29 (450 nm) 0.11 (550 nm) 0.17 (700 nm) (5-min average) (Müller et al., 2011b)
CLAP	0.83 ± 0.02 (FIREX) 0.945 (SGP)	0.199 (FIREX) 0.195 (SGP)	Pallflex E70-2075S and Azumi filter (model 371M) ^c	B _{ATN} and Tr ^d (467, 529, and 653 nm)	60s	30% (Ogren et al., 2017)	0.6 (1-min average), 0.12 (10-min average) (Ogren et al., 2017)
TAP	1.26 ± 0.01	0.253	Azumi filter (model 371M) ^c	B _{ATN} and Tr ^d (467, 528, and 652 nm)	10s	30% (Laing et al., 2016)	2.67 (467 nm) 4.11 (528 nm) 2.13 (652 nm) (30-s average) (Davies et al., 2019)
AETH	2.4	0.5	quartz fiber sampling tape	B _{ATN} and Tr (370, 470, 520, 590, 660, 880, and 950 nm)	120s	10% (Sedlacek, 2016)	0.1 (Sedlacek, 2016)
PSAP	1.0	0.178	Pallflex E70-2075W	B _{ATN} and Tr ^d (470, 522, and 660 nm)	60s	~15% (Bond et al., 1999)	0.3 (Springston, 2016)

228 ^a The detection limits of PAX and PASS-3 are determined by Allan deviation analysis (Allan, 1966) of B_{abs} during “background zero”.

229 ^b During the analysis of the data collected at the SGP, we use B_{abs} derived by the PASS and B_{scat} derived by the NEPH to yield the coefficients in the algorithms.

230 ^c Two types of filters were used during the FIREX campaign (See Sect. 2.1.2).

231 ^d The operating wavelengths of CLAP, TAP, and PSAP are stated slightly different by the instrument manufactures. We simply use 467, 528, and 652 nm throughout
232 this manuscript.

233 2.3. Calibrations

234 Following Bond et al. (1999) and Ogren et al. (2010), the filter-based instruments were calibrated
235 and corrected for sample area, flow rate, and filter type (see Li et al. (2019) for the FIREX data
236 and Sherman et al. (2015) for the SGP data). Other than that, we did not do any verification beyond
237 the manufacturer's calibration for the filter-based instruments. The SGP nephelometer
238 measurements were corrected for truncation effects (Sherman et al., 2015). The FIREX
239 photoacoustic measurements were calibrated by ammonium sulfate aerosol and fullerene soot (Li
240 et al., 2019).

241 2.4. The correction algorithms

242 In filter-based instruments, the light intensities transmitted through the sample spot and blank spot
243 of the filter are recorded as I_s and I_b , respectively. The logarithmic ratio of the two intensities at
244 time t is defined as ATN using the Beer-Lambert law:

$$245 \quad \mathbf{ATN}(t) = -100 \times \ln \frac{I_s(t)}{I_b(t)} \quad 1$$

246 where $\mathbf{ATN} = 0$ when beginning a new filter spot ($t = 0$).

247 The ATN can be related to \mathbf{Tr} by normalizing I_s/I_b at time t relative to I_s/I_b at the start of a new
248 filter spot ($t = 0$):

$$249 \quad \mathbf{Tr}(t) = \frac{I_s(t)/I_b(t)}{I_s(0)/I_b(0)} = \exp\left(\frac{-\mathbf{ATN}(t)}{100}\right) \quad 2$$

250 The change of ATN over a time interval (Δt) for the instrument operated at a volume flow rate of
251 Q and spot area of A yields the attenuation coefficient ($\mathbf{B}_{\mathbf{ATN}}$) for that time interval:

$$252 \quad \mathbf{B}_{\mathbf{ATN}} = \frac{A}{Q \times \Delta t} \times \Delta \mathbf{ATN} \quad 3$$

253 $\mathbf{B}_{\mathbf{ATN}}$ is finally converted to $\mathbf{B}_{\mathbf{abs}}$ by applying correction algorithms. The general form of the
254 correction algorithms presented for the PSAP in Bond et al. (1999) and Virkkula et al. (2005) can
255 be summarized as:

$$256 \quad \mathbf{B}_{\mathbf{abs}} = \mathbf{B}_{\mathbf{ATN}} \times f(\mathbf{Tr}) - C_1 \times \mathbf{B}_{\mathbf{scat}} \quad 4$$

257 where $f(\mathbf{Tr})$ is some function of \mathbf{Tr} (that may vary between approaches), correcting for the filter
258 loading effect. C_1 is a constant that may vary with wavelength; specifically, it is a penalty for the
259 light scattering by the particles collected on the filter which may contribute to the quantification
260 of ATN. In most atmospheric and laboratory studies, $\mathbf{B}_{\mathbf{scat}}$ is measured independently, typically
261 using a co-located NEPH.

262 Besides the above mentioned B1999 and V2005 corrections, the constrained two-stream (CTS)
263 correction proposed by Müller et al. (2014) can be also applied on PSAP-similar instruments. The
264 CTS correction was developed based on the relationship between absorption optical depth and $\mathbf{B}_{\mathbf{abs}}$.
265 However, it is not straightforward to reformulate the CTS correction as a function of \mathbf{Tr} as those
266 presented in Eq. (5) and Eq. (6). Thus, we exclude the $\mathbf{B}_{\mathbf{abs}}$ results corrected by the CTS correction
267 in the following analysis. For those who are interested in the $\mathbf{B}_{\mathbf{abs}}$ results corrected by the CTS
268 correction, we provide the correction results of our SGP-CLAP data in Fig. S9.

269 2.4.1. The B1999 correction

270 Bond et al. (1999) was the first study to present the correction algorithm for filter-based
271 instruments. This empirical correction was originally developed for the PSAP operated at 550 nm
272 using various mixtures of laboratory-generated nigrosin ($SSA \approx 0.5$) and ammonium sulfate (SSA
273 ≈ 1) with B_{abs} ranged from 0 to 800 Mm^{-1} .

274 After calibrating the flow rate and spot area of the PSAP, Bond et al. (1999) derived $C_1 = 0.016$
275 and defined $f(Tr)$ as follows:

$$276 \quad f(Tr)_{B1999} = \frac{1}{C_2 \times Tr + C_3} \quad 5$$

277 Following an adjustment by Ogren (2010), C_2 and C_3 in Eq. (5) were updated to 1.55 and 1.02,
278 respectively. These are the values used in the present work (Table 2) for B1999. Moreover, Ogren
279 (2010) stated that the correction forms of Eq. (4) and Eq. (5) were valid for any wavelength, while
280 additional experiments were needed to establish the equation parameters for the wavelengths other
281 than 574 nm.

282 2.4.2. The V2005 correction

283 Virkkula et al. (2005) developed a correction algorithm for both three-wavelength PSAP (467, 530,
284 and 660 nm) and one-wavelength PSAP (574 nm) using the same functional form as Eq. (4). Since
285 the operating wavelengths of the photoacoustic instruments and the NEPH were different from
286 those of the PSAP, the measured photoacoustic B_{abs} and B_{scat} was extrapolated or interpolated to
287 467, 530, and 660 nm, using inferred AAE and SAE respectively. In this study, the authors used
288 various mixtures of kerosene soot, ammonium sulfate, and polystyrene latex (SSA ranged from
289 0.2 to 0.9) with B_{abs} ranging from 0 to 800 Mm^{-1} at 530 nm.

290 Different from the $f(Tr)$ in the B1999 correction which was a reciprocal function of Tr , the $f(Tr)$
291 presented in V2005 was a multivariate linear function of the natural logarithm of Tr and SSA
292 (including an interaction term between the two):

$$293 \quad f(Tr(\lambda), SSA(\lambda))_{V2005} = C_4 + C_5 \times (C_6 + C_7 \times SSA(\lambda)) \times \ln(Tr(\lambda)) \quad 6$$

294 where the parameters in Eq. (6) vary with wavelengths. The parameters in V2005 were updated in
295 Virkkula (2010) by correcting for flowmeter calibration (Table 2).

296 Due to the unknown values of SSA before deriving B_{abs} , Virkkula et al. (2005) provided a solution
297 through an iterative procedure. In the iteration, B_{abs} is first calculated using the B1999 correction
298 (e.g., Eq. (4) and Eq. (5)) and is then used to compute the initial guess of SSA for use in Eq. (6).
299 The B_{abs} and SSA can be updated using Eq. (4) and Eq. (6) until convergence is reached.

300 2.4.3. Refitting the coefficients in B1999 and V2005

301 With the reference measurements of B_{abs} from the photoacoustic instruments, we are able to refit
302 the coefficients in the B1999 and V2005 corrections (C_2 to C_7 in Eq. (5) and Eq. (6)) using our
303 data. Specifically, we use the Levenberg-Marquardt algorithm (1944) to iteratively fit the
304 coefficients until the chi-square of the coefficients are minimized. The fitting is implemented using
305 the “Curvefit” function in Igor Pro. It is worth noting that the derived coefficients may only be
306 valid for the SGP and FIREX data. For aerosol properties different from our study, the optimal
307 coefficients are likely to be different from the ones reported here. Hereafter, the B1999 and V2005

308 results with refitted coefficients are referred to as “updated B1999” and “updated V2005”,
 309 respectively.

310 2.4.4. The new correction

311 We develop a set of new correction algorithms with the same general form as Eq. (4) using the
 312 biomass burning emissions from 65 different burns during the FIREX laboratory study, providing
 313 a broader range of aerosol optical properties and aerosol concentrations than previous work. This
 314 was motivated by the disagreement that remained between filter-based and photoacoustic
 315 instruments, even after applying B1999 to the data (e.g., see Li et al. (2019) Fig. 4 and our Fig. 2
 316 below). These differences may persist because we were effectively extrapolating the B1999
 317 correction equation to values outside the range for which it was developed.

318 This new correction is developed based on multiple linear regression techniques with three
 319 dependent variables of $\ln(\text{Tr})$, SSA, and AAE and one independent variable of $B_{\text{abs}}/B_{\text{ATN}}$ (Eq. (7)
 320 – (9)). As with other correction equations, this model takes into account the influence of scattering
 321 and weakly-absorbing materials, but we have the additional aim of developing a model that is
 322 applicable to any filter-based absorption photometer.

323 Similar to the B1999 and V2005 corrections, this new model starts with the general form of Eq.
 324 (4), re-written here to define B_{scat} in terms of SSA and B_{abs} .

$$325 \quad \mathbf{B}_{\text{abs}}(\lambda) = \mathbf{B}_{\text{ATN}}(\lambda) \times f(\mathbf{Tr}(\lambda)) - C_1 \times \frac{\text{SSA}(\lambda)}{1 - \text{SSA}(\lambda)} \times \mathbf{B}_{\text{abs}}(\lambda) \quad 7$$

326 Re-arranging this equation to move all B_{abs} terms to the left-hand side yields:

$$327 \quad \mathbf{B}_{\text{abs}}(\lambda) = \mathbf{B}_{\text{atn}}(\lambda) \times g(\mathbf{Tr}(\lambda), \text{SSA}(\lambda)) \quad 8$$

$$328 \quad \text{where } g(\mathbf{Tr}(\lambda), \text{SSA}(\lambda)) = f(\mathbf{Tr}(\lambda)) \times \frac{1 - \text{SSA}(\lambda)}{1 - (1 - C_1) \times \text{SSA}(\lambda)}.$$

329 We define a new function “g” that can be used in Eq. (8). Specifically, we construct a multivariate
 330 linear model for “g”, introducing AAE as a dependent variable and including interaction terms
 331 between SSA, AAE, and $\ln(\text{Tr})$:

$$332 \quad g(\mathbf{Tr}(\lambda), \text{SSA}(\lambda), \text{AAE}) = G_0 + G_1 \times \ln(\mathbf{Tr}(\lambda)) + G_2 \times \text{SSA}(\lambda) + G_3 \times \text{AAE} + G_4 \times \ln(\mathbf{Tr}(\lambda)) \times \text{SSA}(\lambda) + \\ 333 \quad G_5 \times \text{SSA}(\lambda) \times \text{AAE} + G_6 \times \ln(\mathbf{Tr}) \times \text{AAE} + G_7 \times \text{SSA}(\lambda) \times \text{AAE} \times \ln(\mathbf{Tr}(\lambda)) \quad 9$$

334 Equation (9) suggests that different combinations of SSA, AAE and $\ln(\text{Tr})$ can result in the same
 335 value of “g” (i.e., $B_{\text{abs}}/B_{\text{ATN}}$); likewise, a given value of $B_{\text{abs}}/B_{\text{ATN}}$ may have infinitely many points
 336 with distinct slopes passing through it (Fig. S3). Although Eq. (9) is developed based on statistical
 337 approaches, we attempt to relate this statistical model to physical effects. The coefficients $G_1 - G_3$
 338 are fairly straightforward, as these account for the influence of filter loading (G_1), relative light
 339 scattering by the aerosols (G_2), and the brownness of the aerosols (G_3). The interaction terms (G_4
 340 – G_7) are more difficult in assigning a physical meaning; however, the interaction between filter
 341 loading and relative light scattering (G_4) is might be interpreted as an absolute light scattering by
 342 the aerosols on the filter, while the interaction between filter loading and aerosol brownness (G_6)
 343 is somewhat analogous to G_4 . The three-way interaction between filter loading, scattering and
 344 brownness of aerosols (G_7) is required because of the three two-way interaction terms.

345 To further this physical interpretation of our statistical model (Eq. 9), we explore the relationship
 346 between $\frac{B_{abs}}{B_{ATN}}$ and $\ln(\text{Tr})$, which essentially follows a “ $y = m \cdot x + b$ ” form, where y is $\frac{B_{abs}}{B_{ATN}}$ and x is
 347 $\ln(\text{Tr})$. The slope (m) is defined as $G_1 + G_4 \times \text{SSA} + G_6 \times \text{AAE} + G_7 \times \text{SSA} \times \text{AAE}$, and the intercept
 348 (b) is defined as $G_2 \times \text{SSA} + G_3 \times \text{AAE} + G_5 \times \text{SSA} \times \text{AAE}$. Therefore, different combinations of SSA
 349 and AAE modulate this relationship between $\frac{B_{abs}}{B_{ATN}}$ and $\ln(\text{Tr})$. For example, loading “black”
 350 particles on the filter (e.g., AAE ~ 1 and SSA ~ 0.3) tends to produce larger values of $\frac{B_{abs}}{B_{ATN}}$, while
 351 loading “white” particles on the filter (e.g., AAE ~ 3 and SSA ~ 0.9) tends to produce smaller values
 352 of $\frac{B_{abs}}{B_{ATN}}$ (see Fig. S3 of this work and Fig. 4 in Virkkula et al.(2005)). This relationship becomes
 353 more complex when considering, e.g., mixed sulfate and black carbon particles; SSA can be high
 354 while AAE is low, and the corresponding $\frac{B_{abs}}{B_{ATN}}$ can be variable (also see Fig. S3). Therefore, in
 355 order to properly compensate for the effects of loading and aerosol optical properties, a multiple
 356 linear regression with interaction terms is introduced in Eq. (9).

357 A detailed description of the procedure for the model development (e.g., variable transformation
 358 (from Tr to $\ln(\text{Tr})$), variable selection using best-subsets and stepwise approaches, and model
 359 assessment) is provided in the Supplementary Material. We evaluate the model by plotting $\frac{B_{abs}}{B_{ATN}}$
 360 against aerosol properties not included in Eq. (9) (such as relative humidity and aerosol geometric
 361 mean diameter, which have been previously reported to bias corrections of filter-based B_{abs} ,
 362 (Moteki et al., 2010; Nakayama et al., 2010; Schmid et al., 2006)). The results are presented in Fig.
 363 S5-S7.

364 As in V2005, iteration is required in our algorithm because B_{abs} is dependent on knowledge of
 365 SSA and AAE, which themselves are dependent on B_{abs} . We propose the following iterative
 366 process to update SSA and AAE in the model.

- 367 1. Initialize AAE from B_{ATN} across the three wavelengths ($B_{ATN} \sim \lambda^{-AAE}$) and initialize SSA for
 368 each wavelength using B_{ATN} from the filter-based absorption photometer and B_{scat} from a co-
 369 located NEPH, i.e., $SSA(\lambda) = \frac{B_{scat}(\lambda)}{B_{scat}(\lambda) + B_{ATN}(\lambda)}$.
- 370 2. Yield an initial set of coefficients G_0 through G_7 for each wavelength to calculate $g(\text{Tr}, \text{SSA},$
 371 $\text{AAE})$ in Eq. (9), using one of the Algorithms described in Sect. 2.5.
- 372 3. Calculate B_{abs} for each wavelength using Eq. (8).
- 373 4. Update AAE and SSA using B_{abs} calculated in Step 3.
- 374 5. Derive a new set of coefficient values.
- 375 6. Iterate Steps 3-5 until converged.

376 **Table 2** Overview of the studies of B1999 and V2005 and the description of our experiments.

Study	Aerosol source	SSA subset	Range of B_{abs} (Mm^{-1})	Filter-based instrument for B_{abs}	Reference instrument for B_{abs} ^a	Instrument for B_{scat} ^a	Coefficient values in the correction algorithm ^{b, c}		
The study in B1999	Lab-generated aerosols, including various mixtures of nigrosin and ammonium sulfate	0.5-1 (550 nm)	0-800 (550 nm)	One- λ PSAP (550 nm)	The difference between extinction (OEC) and scattering coefficient (NEPH) ^d	NEPH (450, 550, and 700 nm)	$C_1 = 0.016 \pm 0.023$ (550 nm) $C_2 = 1.55 \pm 0.25$ (550 nm) $C_3 = 1.02 \pm 0.17$ (550 nm)

377 ^a The operating wavelengths are based on the manufacturer specifications.
 378 ^b The coefficients provided in Table 2 are the values presented in Ogren (2010) and Virkkula (2010), which are updated from Bond et al. (1999) and Virkkula et al. (2005),
 379 respectively.
 380 ^c We reformulate the correction equations in the original publications to agree with Eq. (4)–(6) in this manuscript. C_1 to C_7 are the coefficients in the present work.
 381 ^d OEC is optical extinction cell and PA is the instrument using photoacoustic technique.
 382 ^e RAOS and NEAQS are Reno Aerosol Optics Study and New England Air Quality Study, respectively.
 383 ^f The relative humidity (%) of the sampled aerosols from the FIREX and SGP study is 29.3 ± 3.3 and 26.1 ± 13.94 , respectively.
 384 ^g The scatterplot of AAE and SAE for the SGP data can be found in Fig. S15. Our results of AAE and SAE are compared to the values reported for different NOAA Earth
 385 System Research Laboratory (ESRL) observational sites in Schmeisser et al. (2017).

386 2.5. Application of correction algorithms

387 In developing a procedure for applying our algorithm, we envision three potential scenarios:

- 388 1. Algorithm A: The filter-based instrument is co-located with a NEPH and reference instrument
 389 providing B_{abs} . This scenario facilitates the computation of G_0 through G_7 in Eq. (9) (step 2 in
 390 the iterative process) as well as the derivation of new coefficients for existing correction
 391 algorithms. This scenario can also enable the develop of a new a set of coefficients that may
 392 be more appropriate for aerosol sources that we do not consider here.
- 393 2. Algorithm B: The filter-based instrument is co-located with a NEPH but not a reference
 394 instrument providing B_{abs} , which is perhaps the most likely scenario (at least at many long-
 395 term monitoring sites). This scenario requires an initial guess of the coefficients; we provide
 396 sets of these in Table 4 below for different filter-based instruments and aerosol sources.
- 397 3. Algorithm C: The filter-based instrument is deployed with neither a co-located NEPH nor a
 398 reference instrument providing B_{abs} . This scenario is the most challenging, because there are
 399 no measurements of B_{scat} to compute SSA; to address this issue, we propose the use of a non-
 400 linear relationship between SSA and AAE ($AAE = a + b \times SSA^c$) to provide an initial guess of
 401 SSA in the iterations.

402 To aid in decision-making between algorithms, we developed a flow chart for selecting appropriate
 403 correction algorithm for CLAP, TAP, and PSAP (Fig. 1). Furthermore, Igor Pro (WaveMetrics,
 404 Inc.) and Python (Version 3.7.5) based program for selecting and implementing our correction
 405 algorithms can be found at <https://doi.org/10.5281/zenodo.3742342>.

406
 407 **Figure 1.** The flow-chart for the application of correction algorithms on PSAP, CLAP, and TAP.
 408 Similar logic is followed for the AETH.

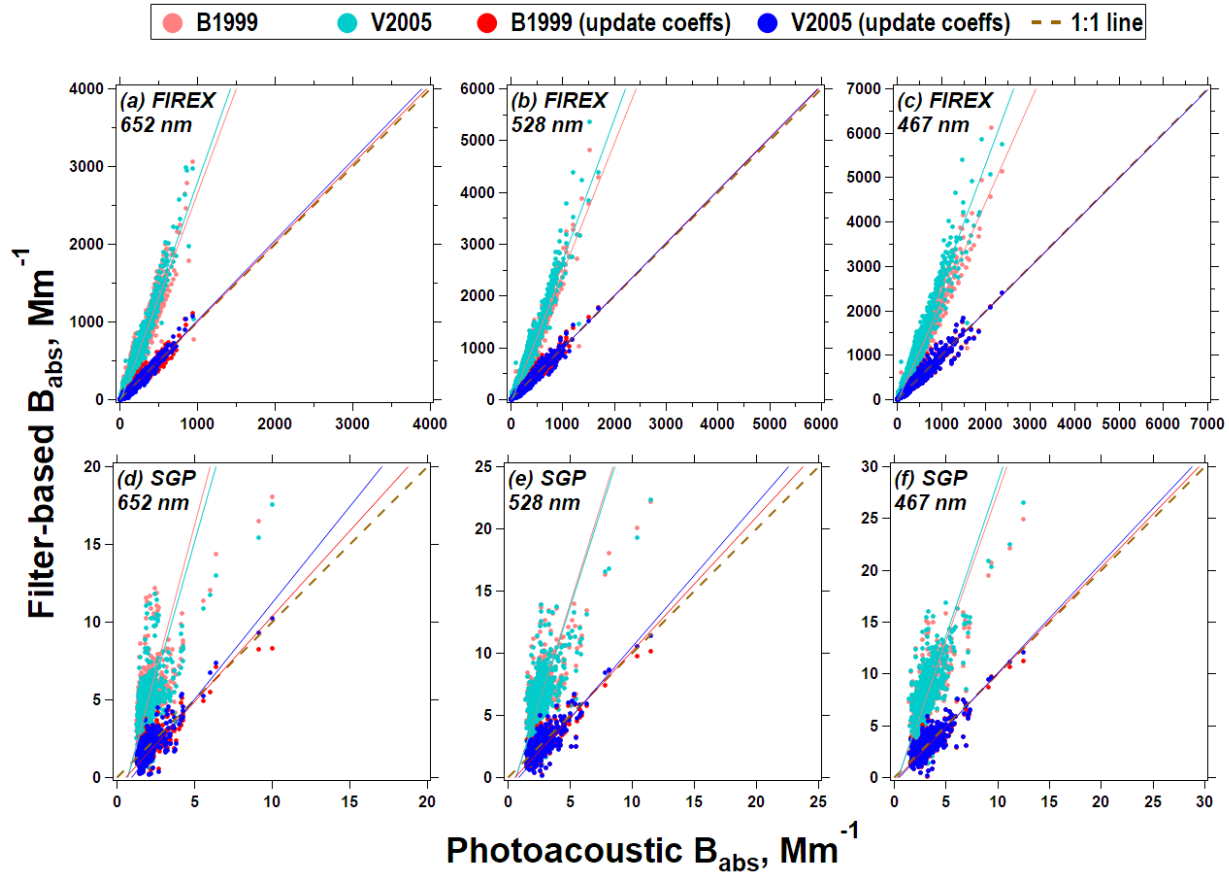

409 3. Results and discussion

410 3.1. Application of the previous algorithms on different aerosols

411 We first consider the application of the B1999 and V2005 corrections on different combinations
 412 of aerosol type and filter-based absorption photometer. Specifically, we apply the two corrections
 413 to the biomass burning data from the FIREX laboratory campaign (CLAP and TAP) as well as six

414 months of ambient data from the SGP site (CLAP and PSAP). In doing so, we use the “default”
415 coefficients recommended in B1999 and V2005 as well as “updated” coefficients that are
416 estimated via regression techniques. It is important to keep in mind that the updated coefficient
417 values of B1999 and V2005 (Table S7) are only valid for the aerosols investigated in this study.
418 Future experiments are needed to systematically determine how the coefficients in B1999 and
419 V2005 may change for different aerosol types. We focus on the results of the CLAP in the main
420 text, because a CLAP is the only instrument common to deployments for both FIREX and SGP.
421 The results of the TAP from FIREX and the PSAP from the SGP site can be found in the
422 Supplementary Material (Table S5 and Fig. S11).

423 Our inter-comparison between the corrected CLAP-derived B_{abs} and reference B_{abs} for the FIREX
424 and SGP data is provided in Fig. 2 and Table 3. For the FIREX measurements, both analyses (using
425 the “default” coefficients and updating the coefficients) suggest good correlation (coefficient of
426 determination (R^2) > 0.9) between the CLAP and the reference across all three wavelengths.
427 Nevertheless, the corrections using the “default” coefficients result in over-prediction of B_{abs} by
428 factors of ~ 2.5 . If we update the coefficients in the corrections, there is an obvious improvement
429 in the agreement (i.e., slope ≈ 1 ; R^2 increases). The results are generally similar for SGP, although
430 the R^2 for ambient data is generally lower for ambient data ($R^2 < 0.7$). Decreased R^2 may be due
431 to the lower aerosol concentrations measured in ambient air, which could lead to lower signal-to-
432 noise in the instruments. Moreover, it is worth mentioning that for both datasets (FIREX and SGP),
433 the corrected B_{abs} from different filter-based absorption photometers using the “default”
434 approaches does not agree with each other (slopes range from 0.69 to 1.40). However, after
435 updating the coefficients, the slopes approach unity (Table S6).

436

437 **Figure 2.** Inter-comparison between the CLAP-derived B_{abs} corrected by the B1999 and V2005
 438 algorithms and the reference B_{abs} at 652, 528, and 467 nm for both FIREX and SGP data. The solid
 439 lines represent linear regressions, while the dashed line is a 1:1 line.

440 **Table 3** Relationship between the CLAP-derived B_{abs} corrected by the B1999 and V2005
 441 algorithms (including updated coefficients) and the reference B_{abs} at 652, 528, and 467 nm. The
 442 relationship is achieved using major axis regression (Ayers, 2001). The value in parentheses
 443 represents the coefficient of determination (R^2) of the linear relationship.

		652 nm	528 nm	467 nm
FIREX	B1999	$y = -39 + 2.69x$ (0.94)	$y = -49 + 2.50x$ (0.96)	$y = -45 + 2.26x$ (0.97)
	V2005	$y = -46 + 2.83x$ (0.96)	$y = -57 + 2.75x$ (0.96)	$y = -56 + 2.68x$ (0.96)
	B1999 (update coeffs)	$y = -8.4 + 1.02x$ (0.96)	$y = -7.7 + 1.01x$ (0.97)	$y = -3.4 + 1.00x$ (0.96)
	V2005 (update coeffs)	$y = -9.4 + 1.03x$ (0.97)	$y = -7.3 + 1.01x$ (0.97)	$y = -3.0 + 1.00x$ (0.96)
SGP	B1999	$y = -2.60 + 3.77x$ (0.41)	$y = -1.90 + 3.20x$ (0.49)	$y = -0.98 + 2.85x$ (0.55)
	V2005	$y = -2.50 + 3.54x$ (0.41)	$y = -2.00 + 3.15x$ (0.48)	$y = -1.10 + 2.96x$ (0.55)
	B1999 (update coeffs)	$y = -0.29 + 1.10x$ (0.60)	$y = -0.29 + 1.08x$ (0.63)	$y = -0.17 + 1.03x$ (0.65)
	V2005 (update coeffs)	$y = -0.57 + 1.24x$ (0.65)	$y = -0.50 + 1.15x$ (0.67)	$y = -0.27 + 1.06x$ (0.67)

444

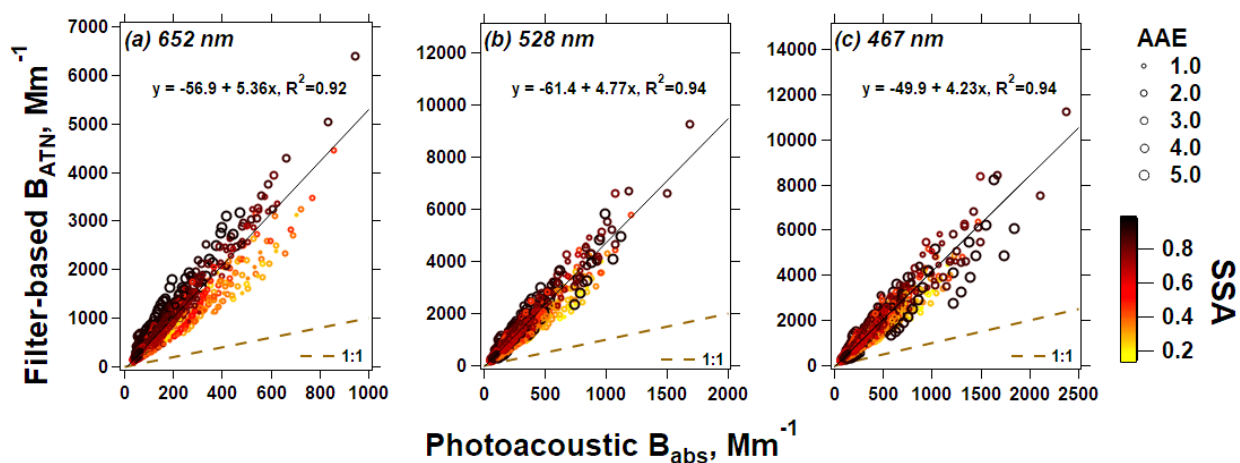

445 In the FIREX data, there is an apparent dependency of the updated coefficients on the wavelength
 446 of light, but more importantly, on the aerosol optical properties, namely SSA and AAE (Tables
 447 S7-S9). However, in the ambient data from SGP, the dependency on optical properties is less

448 obvious (Tables S10-S11). Nevertheless, all of these coefficients differ from those reported in
449 B1999 and V2005 (again, derived for the PSAP rather than the CLAP), which highlights the
450 potential need to use coefficient values that are appropriate for the instrument being used, its
451 wavelength(s) of light, and optical properties that are representative of the sampled aerosols when
452 applying correction factors to B_{ATN} .

453 3.2. Application of the new algorithms to the FIREX data

454 The co-location of the CLAP, TAP, AETH, and PAX during FIREX allows us to apply each
455 algorithm (A, B, C) to these data. Similar to Sect. 3.1, we focus our discussion on the CLAP with
456 details on the TAP and AETH presented in the Supplementary Material (Fig. S11-S12). However,
457 we provide the recommended initial guesses in the new algorithms and the comparison of
458 absorption (corrected filter-based B_{abs} versus reference B_{abs}) for all filter-based absorption
459 photometers in Table 4 and Table 5 to help readers quickly retrieve key information of our
460 algorithms.

461 Figure 3 provides a comparison between the uncorrected B_{ATN} from the CLAP at all three
462 wavelengths, as well as photoacoustic B_{abs} interpolated to those wavelengths using AAE. For each
463 wavelength, the slopes are significantly greater than one. Moreover, there is an apparent
464 dependency on SSA and AAE in the agreement between the instruments. This is most obvious in
465 Fig. 3a (652 nm), where data with lower SSA and lower AAE (smaller markers, “brighter” colors)
466 fall below the best-fit line, while data with higher SSA and higher AAE (larger markers, “darker”
467 colors) fall above the best-fit line. This phenomenon is less clear in Fig. 3b-3c, but an apparent
468 dependency on SSA and AAE remains, which highlights the need to include both of these aerosol
469 optical properties (and appropriate interaction terms) when correcting B_{ATN} values.

470
471 **Figure 3.** Comparison of the uncorrected CLAP-derived B_{ATN} and the reference B_{abs} at 652, 528,
472 and 467 nm for the FIREX data. The data points are colored by the corresponding SSA at the given
473 wavelength. The size of data points reflects their AAE quantified by the two PAX. The solid line
474 represents the linear regression, while the dashed line is a 1:1 line.

475 We first apply “Algorithm A” to the CLAP B_{ATN} data in Fig. 3. Using the reference B_{abs} values
476 from the PAX (in addition to B_{scat} values), we are able to derive a set of coefficients that enable
477 the correction of the data (Table 4). Corrected CLAP values are presented in Fig. 4 with the linear

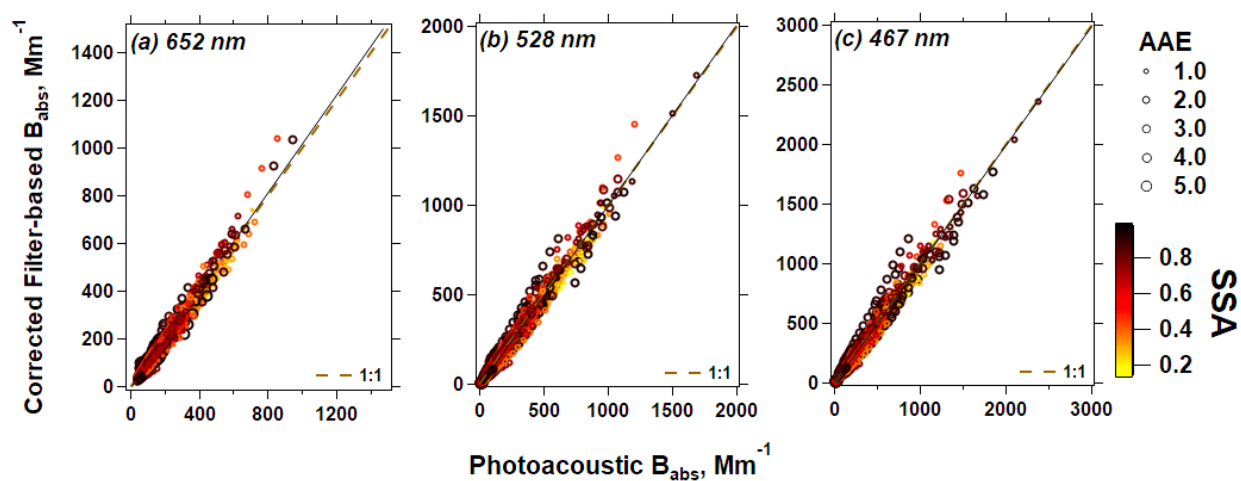

478 relationships presented in Table 5. The slope for each wavelength is very close to the 1:1 line,
 479 suggesting that our approach works well in correcting these data. Moreover, the heteroscedasticity
 480 that exists in Fig. 3 has been minimized after correction, and there are no apparent trends in how
 481 the data are organized in Fig. 4 due to the aerosol optical properties.

482 **Table 4** Coefficient values for Eq. (9) derived using “Algorithm A”. We recommend these as the
 483 initial guesses when implementing “Algorithm B”^a.

484 ^aThe coefficients derived from FIREX may be more appropriate for biomass burning aerosols, and
 485 the coefficients derived from SGP may be more appropriate for rural background environments in
 486 the absence of marine aerosols and dust (see Fig. S15).

487

488

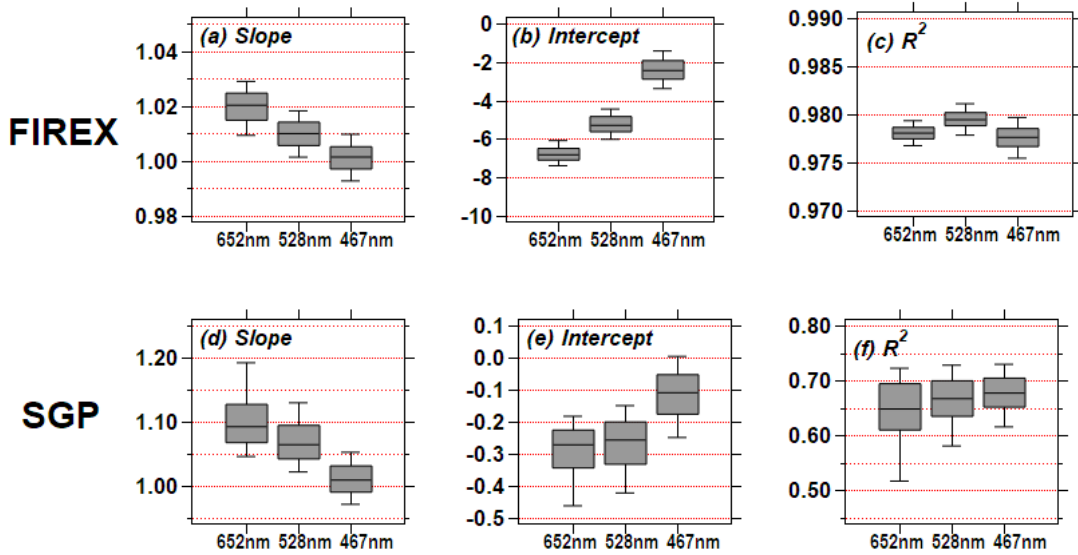

489 **Figure 4.** As in Fig. 3, but the CLAP-based B_{ATN} values have been corrected using our “Algorithm
 490 A”.

491 **Table 5** Relationship between the filter-based B_{abs} corrected by “Algorithm A” and the reference
 492 B_{abs} at the operating wavelengths for the filter-based instrument. The relationship is achieved using
 493 major axis regression (Ayers, 2001). The value in the parentheses represents the coefficient of
 494 determination (R^2) for the linear relationship.

495
 496 We next investigate the repeatability of the coefficient values presented in Table 4 by randomly
 497 selecting half of the measurements ($N = 1338$) from the whole FIREX dataset. By implementing
 498 “Algorithm A” to the extracted observations, we obtain new coefficient values for G_0 to G_7 . This
 499 is repeated 1000 times to obtain a distribution of coefficient values (Fig. S13). The extraction
 500 approach mimics the process of obtaining new biomass burning datasets, so that we can estimate
 501 the variability of these derived coefficients. From Fig. S13 and Table S12, the derived coefficients
 502 are mostly insensitive to the different randomly-extracted datasets; most of the quartile deviation
 503 (defined as $(Q3-Q1)/2$, where $Q1$ and $Q3$ are the first and third quartile respectively) is within 0.05,
 504 except G_4 which has a quartile deviation of ~ 0.08 . Consequently, the coefficient values obtained
 505 in “Algorithm A” appear to be reasonable initial guesses to correct filter-based absorption
 506 measurements during biomass burning events when the reference B_{abs} is unavailable, such as in
 507 “Algorithm B” and “Algorithm C”.

508 We next implement “Algorithm B” to the CLAP B_{ATN} data from Fig. 3 using the initial guesses of
 509 the coefficients derived from “Algorithm A” (Table 4) along with reference B_{scat} values. To get a
 510 sense of the variability in the results, we randomly select half of the data and applied the correction;
 511 this process is repeated 1000 times. For each iteration, we compare the corrected B_{abs} from the
 512 CLAP to the reference B_{abs} from the PAX; the resulting slope, intercept, and R^2 values are
 513 summarized as box-and-whisker plots in Fig. 5. For all three wavelengths, the slopes are close to
 514 unity, and there is good correlation between the two absorption measurements ($R^2 \approx 0.98$), which
 515 indicates that the good performance seen in Fig. 4 is independent of the reference B_{abs}
 516 measurements and our algorithm is able to correct “new” B_{ATN} . Consequently, when scattering
 517 measurements are co-located with filter-based absorption measurements, our new correction
 518 algorithm performs well.

519

520 **Figure 5.** The box-and-whisker plots for the slope, intercept, and R^2 of the relationship between
 521 the CLAP-derived B_{abs} (corrected by “Algorithm B” in the present work) and PAX-derived B_{abs} for
 522 all three wavelengths. For details on how these values were generated, please refer to the text.

523 Lastly, we apply “Algorithm C” to the data in Fig. 3. However, we first require a functional
 524 relationship between AAE and SSA, because in this scenario, the CLAP B_{ATN} values are the only
 525 data input to the algorithm (and therefore, SSA is unknown). Liu et al. (2014) proposed that a
 526 power function can describe this relationship ($AAE = a + b \times SSA^c$); we present these data from
 527 FIREX along with power function fits (and associated prediction intervals) in Fig. 6. To define
 528 AAE in this figure, we fit a power-law relationship to the three B_{ATN} values from the CLAP;
 529 similarly, we define SSA using interpolated B_{scat} from the PAX and B_{ATN} from the CLAP (The
 530 rationale for using B_{ATN} is that if “Algorithm C” were to be implemented in practice, only B_{ATN}
 531 would be available). In Fig. 6, the data points are colored by “prediction error”, effectively a metric
 532 to quantify how well the power function reproduces the individual data points. Although there is
 533 a fair amount of error in some of these points, we still obtain an SSA-AAE relationship required
 534 to initialize “Algorithm C”.

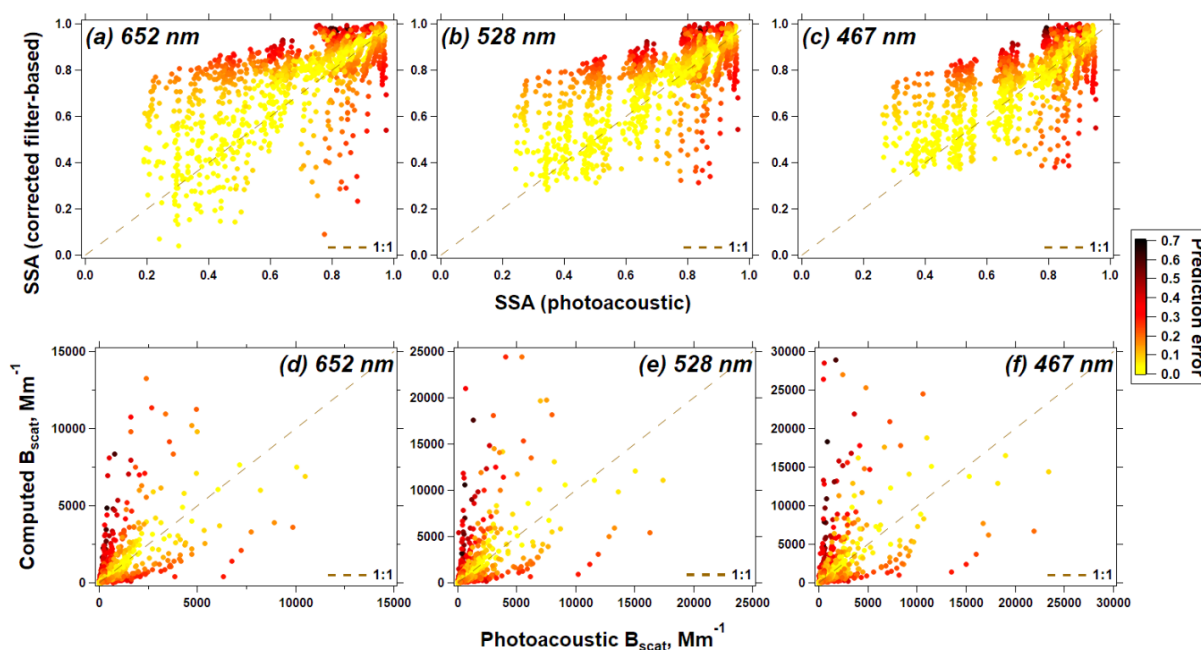

535

536 **Figure 6.** AAE plotted against SSA for the FIREX data. In the figures, AAE was computed using a
 537 power-law fit across all three wavelengths, and SSA was computed using the interpolated B_{scat}

538 from the two PAX and the reported B_{ATN} from the CLAP. The data points are colored by their
539 prediction error ($(\text{“true” AAE} - \text{“calculated” AAE}) / \text{“calculated” AAE}$).

540 Even though there is uncertainty in the SSA vs. AAE relationship used in “Algorithm C”, after
541 corrections have been applied, the filter-based B_{abs} for the CLAP agrees well with the independent
542 reference B_{abs} ; the slopes for all wavelengths are slightly greater than 1 (1.03-1.05) and the R^2
543 values are all high (0.97-0.98). However, even though the absorption measurements are corrected
544 well, there still remains large uncertainties in values of inferred scattering. Examples of this are
545 provided in Fig. 7, where we compare the SSA inferred from the PAX to the SSA inferred from
546 “Algorithm C” as well as B_{scat} for each wavelength. Generally speaking, data that are better
547 represented by the SSA vs. AAE relationship (i.e., smaller prediction error) results in better
548 agreement with the reference for both SSA and B_{scat} , but there is also a clear divergence from the
549 1:1 line in Fig. 7a-c as SSA decreases. Therefore, even though “Algorithm C” performs well at
550 correcting filter-based B_{ATN} to agree with the reference B_{abs} , estimates of final SSA values should
551 be considered to be uncertain.

552
553 **Figure 7.** Comparison of SSA (a-c) and B_{scat} (d-f) at the three wavelengths for the FIREX data.
554 Vertical axis: values output from “Algorithm C”; horizontal axis: values calculated using the
555 photoacoustic B_{abs} and B_{scat} .

556 To explore the generalization of the new algorithms across different instruments, we next apply
557 our algorithms to the other filter-based absorption photometers operated during the FIREX study
558 (TAP and AETH). Consistent with what we observed for the CLAP results, the corrected TAP-
559 and AETH-derived B_{abs} is in good agreement with the photoacoustic B_{abs} (as demonstrated in Table
560 4 and Table 5, as well as Fig. S11-S12). Moreover, the corrected B_{abs} from the three filter-based
561 instruments agrees with each other for all three wavelengths (Table 6), confirming the consistency
562 of our algorithm.

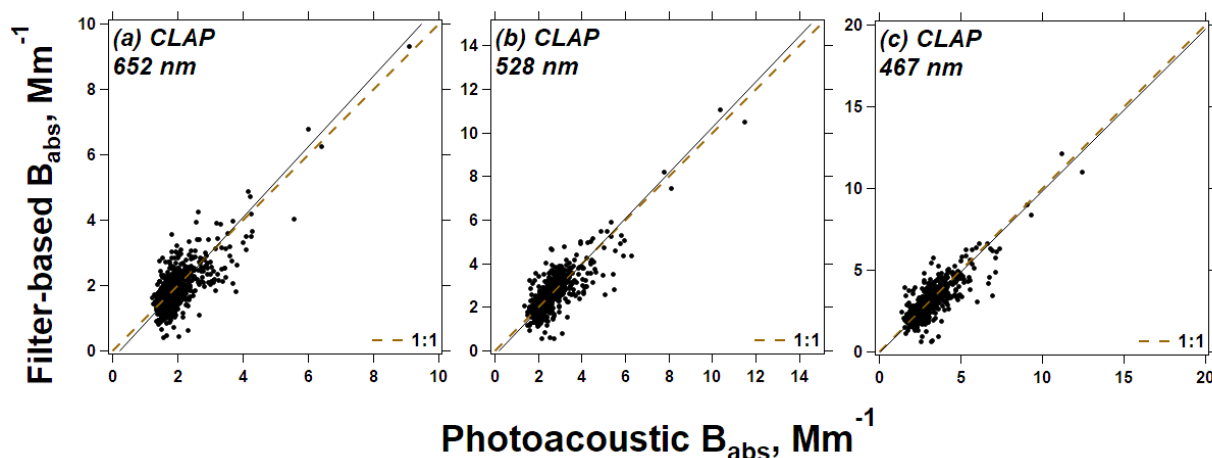

563 **Table 6** Inter-comparison between different filter-based B_{abs} corrected by “Algorithm A” in the
 564 present work. The value in the parentheses represents the coefficient of determination (R^2) of the
 565 linear relationship.

	FIREX: CLAP vs. TAP	FIREX: CLAP vs. AETH	FIREX: TAP vs. AETH	SGP: CLAP vs. PSAP
652 nm	$y = 1.84 + 1.02x$ (0.89)	$y = 4.17 + 0.94x$ (0.87)	$y = -0.31 + 0.99x$ (0.82)	$y = -0.04 + 0.99x$ (0.70)
528 nm	$y = 5.75 + 1.02x$ (0.88)	$y = 3.70 + 0.91x$ (0.85)	$y = -6.38 + 0.98x$ (0.82)	$y = -0.11 + 1.02x$ (0.73)
467 nm	$y = 10.57 + 1.01x$ (0.88)	$y = 0.45 + 0.98x$ (0.83)	$y = -13.62 + 1.04x$ (0.79)	$y = -0.11 + 1.02x$ (0.76)

566

567 3.3. Application of the new algorithms to ambient data

568 To test our algorithms further, we extended our work to ambient data collected the DOE SGP site
 569 during the time period which the PASS-3 was operational. From the SGP data, we derived a
 570 different set of coefficients for ambient data using “Algorithm A”, which differ from those derived
 571 for FIREX (Table 4). The results presented in Fig. 8 and Table 5 suggest that our new algorithm
 572 works at least as well as B1999 and V2005 on this dataset (both with updated coefficients). The
 573 repeatability of the coefficient values in “Algorithm A” is confirmed for the SGP measurements
 574 using the same procedure as described in Sect. 3.2 (see results in Fig. S13 and Table S12).

575

576 **Figure 8.** Inter-comparison between the CLAP-derived B_{abs} corrected by “Algorithm A” in the
 577 present work and reference B_{abs} at 652, 528, and 467 nm for the ambient data at the SGP study
 578 area. The solid line represents the linear regression, while the dashed line is a 1:1 line.

579 On the SGP data, we see similar performance to the FIREX data when we apply “Algorithm B”,
 580 where we again sampled half of the CLAP data, used the initial guesses derived in “Algorithm A”,
 581 and repeated this process 1000 times. Although the slopes tend to be larger than 1 (i.e., the
 582 corrected CLAP B_{abs} remains high relative to the PASS B_{abs}), the results still represent an
 583 improvement over B1999 and V2005 using their recommended coefficients for their correction
 584 equations.

585 Implementing “Algorithm C” is challenging for ambient data, because there is no distinct power
 586 function relationship in AAE vs. SSA (Fig. 9); this is consistent with other field studies reporting
 587 both SSA and AAE (e.g., Backman et al. (2014) and Lim et al. (2018)). Our approach described

588 here is only appropriate for ambient aerosols that follow a power function, such as sites impacted
589 by biomass burning. Nevertheless, we did apply this to a subset of the SGP data where the AAE-
590 SSA prediction error is within 30% ($N = 86$), and for this subset of data, “Algorithm C” works
591 fairly well (slopes ≈ 0.95 ; see Fig. S14). Therefore, while “Algorithm C” may have utility for
592 ambient data, we advise caution when using this algorithm since the aerosols influencing the site
593 may not be represented by a clear AAE-SSA power function (e.g., when biomass burning and
594 coarse aerosols are equally prevalent at a long-term monitoring site).

595
596 **Figure 9.** AAE plotted against SSA for the SGP ambient data. The power law fit ($AAE = a + b \times SSA^c$)
597 is performed on SSA ($SSA = B_{scat}/(B_{scat} + B_{ATN})$) and AAE computed by three-wavelength B_{ATN} .

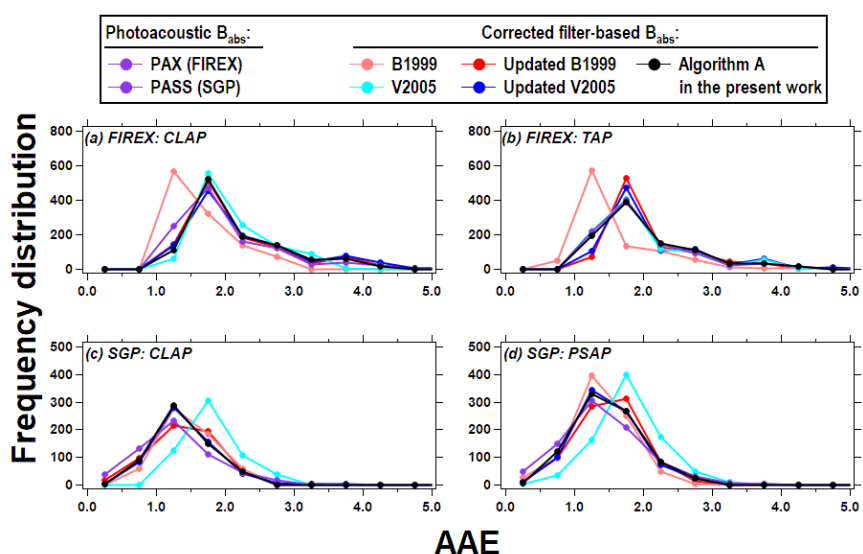

598 These new algorithms are also applicable to the PSAP deployed at the SGP site. The results of the
599 correction for the PSAP are presented in Table 5 and Fig. S11, and the recommended initial guesses
600 when implementing “Algorithm B” to PSAP- B_{ATN} at ambient environments are given in Table 4.
601 As expected, there is good agreement between corrected PSAP- and CLAP- B_{abs} (Table 6).

602 To investigate if our algorithms are suitable to correct B_{abs} obtained from different ambient
603 environments, the aerosol properties from the SGP site are compared to those from the other
604 NOAA/ESRL observational sites. We use the similar “AAE-SAE space” as that in Cappa et al.
605 (2016) and Schmeisser et al. (2017) to infer dominant aerosol types (e.g., BC, BrC, dust, mixed
606 dust/BC/BrC, see Fig. S15). Our results of AAE and SAE overlap with most of the values from
607 the NOAA/ESRL sites, except when marine aerosols or dust contribute to the local aerosol
608 emissions. Though none of the NOAA/ESRL sites fall into the clusters of BC or BC/BrC, some of
609 our data can represent the optical properties of aerosols from these clusters. Therefore, we highlight
610 that our algorithm developed by the SGP data may have the potential to be generalized to a variety
611 of environmental conditions, but we would need to validate this using observations from more
612 studies.

613 3.4. Impact of the implemented correction algorithm on aerosol optical properties

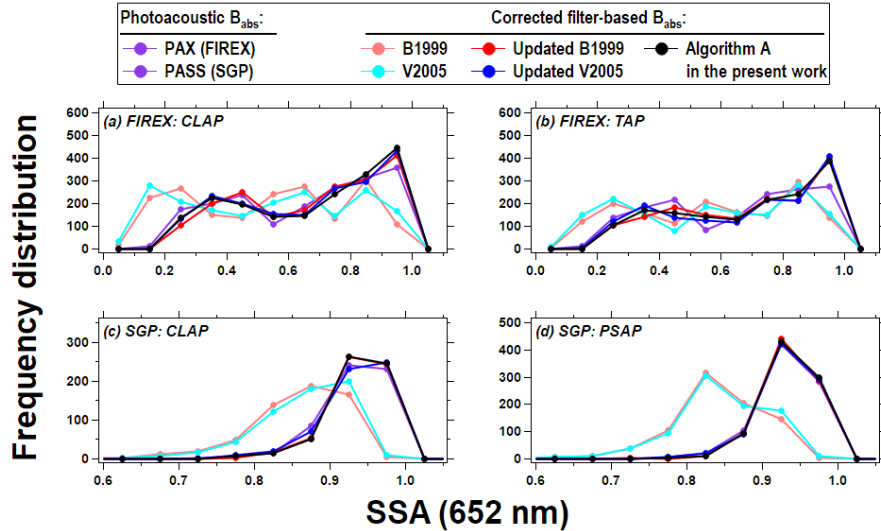

614 In addition to the direct comparisons of B_{abs} between the filter-based and photoacoustic
615 measurements, we compare derived optical properties (AAE and SSA) from different instruments
616 to assess the algorithms’ performance on derived aerosol optical properties. For example, we have
617 discussed the discrepancy of SSA between the filter-based and photoacoustic measurements when
618 implementing “Algorithm C” in Sect. 3.2. In this section we will more broadly discuss the impact
619 of different correction algorithms on AAE and SSA.

620 In Fig. 10, we present the frequency distribution of AAE for both FIREX and SGP data generated
 621 from different campaign/instrument pairs using different correction approaches. For the FIREX
 622 data (Fig. 10a-b), most corrections (with the exception of the “default” B1999) are consistent with
 623 the photoacoustic data, while for the SGP data (Fig. 10c-d), most corrections (with the exception
 624 of “default” V2005) are consistent with the photoacoustic data. However, updating the coefficients
 625 for B1999 and V2005 improves the agreement with the photoacoustic data. The 50% difference
 626 that exists between the B1999 and V2005 algorithms in all panels in Fig. 10 are consistent with
 627 previous studies. For example, both Backman et al. (2014) and Davies et al. (2019) found that the
 628 V2005-derived AAE is greater than B1999-derived AAE by 33% to 50% for ambient aerosols.
 629 Therefore, we highlight that the default coefficients in B1999 and V2005 may have some
 630 limitations when deriving AAE using the corrected B_{abs} ; instead, updating the coefficients or using
 631 the new algorithm proposed in this work may yield more robust AAE results.

632
 633 **Figure 10.** The frequency distribution of AAE calculated for different instrument/correction
 634 combinations of multi-wavelength B_{abs} .

635 Similar to Fig. 10, we also investigate the distribution of SSA computed by using corrected B_{abs}
 636 along with B_{scat} . We provide the results at 652 nm as an example in the main text (Fig. 11); figures
 637 for 528 nm and 467 nm can be found in the Supplementary Material (Fig. S16 and S17). For both
 638 FIREX and SGP data, the SSA obtained using the new algorithm agree very well with the B1999
 639 and V2005 but only when their coefficients have been updated. Calculations of SSA using B1999
 640 and V2005 with their recommended coefficients suggest that these values may be biased low,
 641 which follows the over-estimation of corrected B_{abs} demonstrated in Fig. 2.

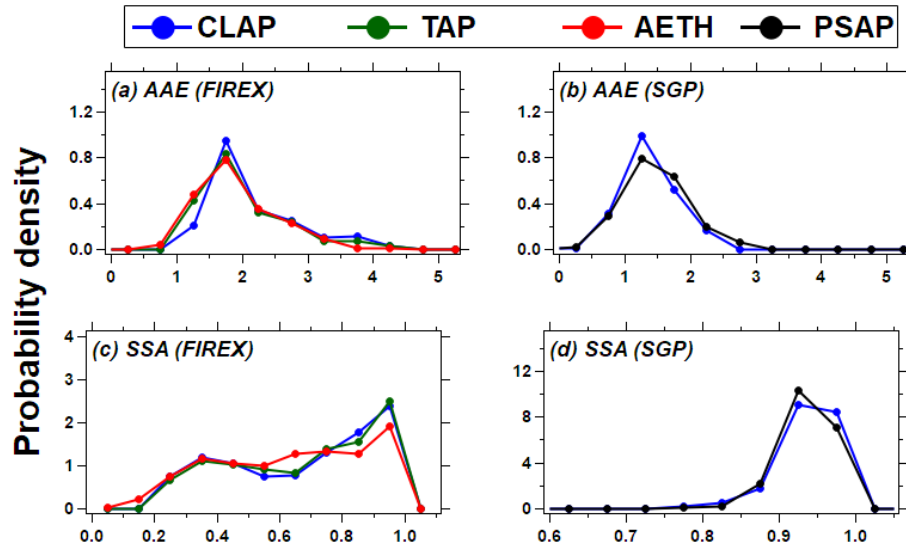

642

643 **Figure 11.** The frequency distribution of SSA (652 nm) calculated for different
 644 instrument/correction combinations of B_{abs} and B_{scat} .

645 Moreover, we plot similar figures as Fig. 10-11 using all algorithms (A, B, and C). As shown in
 646 Fig. S18, the results using “Algorithm B” agrees very well with those using “Algorithm A”, but
 647 the use of “Algorithm C” results in some obvious discrepancies compared to the photoacoustic
 648 reference, again highlighting the potential for large uncertainty using this algorithm.

649 In Fig. 12, we directly compare the distributions of both AAE and SSA at 652 nm for all of the
 650 filter-based absorption photometers considered here, using our “Algorithm A” to correct the B_{ATN}
 651 data. For both datasets, after the corrections have been applied, there are only marginal differences
 652 of the AAE (Fig. 10a and 10b) derived by different instruments. Similarly, there is good agreement
 653 among the SSA values when using corrected- B_{abs} from different instruments (Fig. 10c and 10d).
 654 Overall, the derived properties using the new correction are consistent across all instruments,
 655 suggesting its generalizability.

656

657 **Figure 12** The probability density of AAE and SSA (652 nm) derived by different filter-based
 658 photometers B_{abs} (corrected by “Algorithm A” in the present work). Note that the number of total
 659 observations vary across instruments.

660 3.5. Uncertainty of the new algorithms

661 In this section, we estimate the uncertainty of the new algorithms due to both measurement
 662 uncertainties of the instruments and the uncertainties of parameter computation. We then simulate
 663 the propagated uncertainty in the corrected filter-based B_{abs} reported in this paper.

664 Measurement uncertainties of the instruments considered here have been reported in previous work
 665 (e.g., (Anderson et al., 1996; Nakayama et al., 2015; Ogren et al., 2017; Sherman et al., 2015)) and
 666 are summarized in Table 1. The typical sources of measurement uncertainty of the aerosol
 667 instruments include: 1) instrument noise (often associated with the averaging time); 2) calibration
 668 uncertainties (such as the accuracy of the operating wavelengths and the properties of the
 669 calibration materials); 3) standard temperature and pressure (STP) correction uncertainties
 670 (Sherman et al., 2015); and 4) flow rate uncertainties. Additional uncertainties that are specific to
 671 filter-based absorption photometers include spot size and filter medium corrections (Bond et al.,
 672 1999; Ogren et al., 2017). Regardless, these values all tend to be $\leq 30\%$, which is consistent with
 673 other commonly-used aerosol instrumentation.

674 Because correction algorithms for filter-based absorption instruments also require aerosol optical
 675 properties, the algorithms’ performance will be affected by these values as well. For example,
 676 uncertainties in SSA are directly related to uncertainties associated with B_{abs} and B_{scat} , which are
 677 both included in our simulations. However, capturing uncertainties in AAE is more complex, as
 678 AAE can be computed by either “ 2λ fit” (a linear fit using B_{abs} at two wavelengths) or “ 3λ fit”
 679 (same as the power fit used in the present work). Davies et al. (2019) used the 3λ fit to calculate
 680 AAE and compared this to calculations using 662 nm and 785 nm (i.e., $\text{AAE}_{662/785}$), finding that
 681 the 3λ results was about 50% greater. Moreover, similar differences (-35% to 85%) can exist
 682 comparing two different 2λ combinations ($\text{AAE}_{440/870}$ and $\text{AAE}_{675/870}$), depending on the
 683 contribution of brown carbon to absorption at 440 nm (Wang et al., 2016). However, based on Fig.
 684 S19 and S20, we demonstrate small ($< \sim 10\%$) differences in the calculated values of AAE using

685 our Algorithm A using different 2λ combinations for linear fits and the 3λ power-law fit, when
686 considering both FIREX and SGP data. Consequently, we do not include AAE calculation
687 uncertainty in our simulation.

688 In our simulations, the propagated uncertainty of corrected B_{abs} is estimated by implementing the
689 new algorithm to datasets in which filter-based B_{ATN} , reference B_{abs} , and B_{scat} are subject to
690 measurement uncertainties. The full procedure is outlined in the Supplementary Material, but we
691 provide a brief overview of our Monte Carlo approach here. First, we create a synthetic dataset (n
692 = 500 records) that defines B_{abs} at 652 nm and AAE that is intended to represent biomass burning.
693 Values of B_{ATN} and SSA are then computed using the relationships presented in Fig. 3 and Fig. 6,
694 respectively. Respective uncertainties associated with each of these values are applied following
695 Table 1, assuming that these follow a normal distribution. We then applied “Algorithm B” to the
696 B_{ATN} dataset, repeated 1000 times, to quantify overall uncertainty associated with our correction
697 algorithm.

698 Figure 13 provides a graphical summary of our uncertainty simulation results, which was derived
699 by fitting linear equations to the “true” B_{abs} value (that we defined) and the “corrected” B_{abs} values
700 (outputs of each iteration). Considering the slopes (Fig. 12a), our algorithm can generally
701 reproduce the “true” value within 10% at 652 nm and 528 nm, but the performance is slightly
702 degraded at 467 nm. The median intercept for our simulations is close to zero, but the interquartile
703 range increases with decreasing wavelength (Fig. 12b), suggesting that the uncertainty may
704 increase at shorter wavelengths. The coefficients of determination (Fig. 12c) range from 0.47 (652
705 nm) to 0.68 (467 nm), showing that the algorithm may be less precise if large measurement
706 uncertainties exist. Even though these sources of uncertainty exist when implementing our
707 correction algorithms and propagate through to the corrected values, we argue that our new
708 algorithm will “standardize” uncertainties across corrected B_{abs} values from filter-based absorption
709 photometers. Moreover, the new algorithms perform, at least, better than the previous algorithms
710 with “default” coefficients, or as well as the previous algorithms with updated coefficients.

711
712 **Figure 13.** The box-and-whisker plots (slope, intercept, and R^2) for the Monte Carlo simulation of
713 the relationship between the CLAP-derived B_{abs} (corrected by “Algorithm B” in the present work)
714 and “true” B_{abs} for all three wavelengths.

715 4. Conclusions

716 Filter-based absorption instruments are widely used at global observational sites due to their
717 relatively low cost, fast response, and easy operation. Despite the existence of different correction
718 algorithms to correct the filter-based B_{abs} measurements, these are not “standardized” as
719 differences in corrected B_{abs} values exist across different instrument/correction combinations, even
720 when the instruments are co-located. This study provides a systematic evaluation of the previous
721 correction algorithms (B1999 and V2005 corrections) on the CLAP and similar instruments (TAP
722 and PSAP) using both laboratory-generated biomass burning emissions and ambient aerosols. We
723 also developed new correction algorithms that are applicable to any filter-based absorption
724 photometer (e.g., PSAP, CLAP, TAP, AETH), which will have utility for any historic or future
725 filter-based absorption measurements and which have the potential to standardize absorption
726 coefficients across all filter-based instruments. This latter point is demonstrated in Table 6 and Fig.
727 12 in that there is good agreement across all filter-based absorption photometers when applying
728 our corrections to both biomass burning and ambient data. In practice, we anticipate that our
729 Algorithm B will be most common, because at long-term monitoring sites, filter-based absorption
730 photometers are typically co-located with a nephelometer.

731 Using the existing corrections on our CLAP measurements, we find that the corrected B_{abs}
732 overestimate photoacoustic B_{abs} by factors of ~ 2.6 (biomass burning aerosols) and ~ 3.2 (ambient
733 aerosols). Similar overestimations of absorption by filter-based instruments are seen in the results
734 of TAP from the FIREX study and PSAP deployed at the SGP. Comparing between B1999 and
735 V2005, B_{abs} corrected by the two corrections differ by -6% to 18% . These discrepancies in our
736 results are consistent with those reported for the inter-comparisons between filter-based and
737 photoacoustic absorption instruments (e.g., (Arnott et al., 2003; Davies et al., 2019; Li et al., 2019;
738 Müller et al., 2011a)).

739 Overall, our new developed algorithms (A, B, and C) perform well on correcting B_{abs} for different
740 filter-based absorption photometers (CLAP, TAP, PSAP, and AETH) from both biomass burning
741 and ambient measurements. Our work suggests that if the filter-based instrument is co-operated
742 with a reference absorption instrument and a NEPH at field for a period, researchers can compute
743 site-specific initial guesses (same as “Algorithm A” in the present work). Otherwise, either
744 “Algorithm B” or “Algorithm C” proposed in this paper can be used to correct the filter-based
745 measurements. In “Algorithm B” when a filter-based absorption photometer is co-located with a
746 NEPH but without a reference instrument, the set of coefficients yield in this work (Table 4) can
747 be used as initial guesses to implement the algorithm. In “Algorithm C” when a filter-based
748 absorption photometer is operated by itself, a “representative” relationship between AAE and SSA
749 can be used to estimate SSA from AAE at each step in the iterative process, but we advise caution
750 if this relationship is not monotonic (e.g., as in the ambient data from SGP and from Backman et
751 al. (2014) and Lim et al. (2018)). The only scenario not included in the present work is that the
752 filter-based absorption photometer is co-located with a reference absorption instrument, but no
753 instrument for scattering. However, under this scenario, one could simply use the photoacoustic
754 B_{abs} data because no filter-induced biases exist for those instruments.

755 In terms of the aerosol optical properties (AAE and SSA) computed by different corrections, the
756 new algorithm suggests no bias of AAE and SSA when compared to that derived by updated-
757 B1999 and updated-V2005 for both aerosol datasets.

758 However, the new algorithm is not without limitations. First, we used the photoacoustic B_{abs} as the
759 reference to develop the algorithm and the initial guess of the coefficients; meanwhile, some
760 studies argue that photoacoustic absorption is not a “ground truth” (e.g., (Lack et al., 2006; Lewis
761 et al., 2008)). Thus, we simulate the propagated uncertainty of our algorithms considering the
762 measurement uncertainties due to the photoacoustic B_{abs} (as well as B_{ATN} and B_{scat}) and find that
763 the corrected B_{abs} can be biased by -17% to 5%, depending on the operated wavelength. Although
764 potential bias due to the precision of photoacoustic B_{abs} cannot be excluded, using our new
765 algorithm to correct the filter-based B_{abs} will at least eliminate correction-related biases among
766 different filter-based instruments. Second, we only tested the algorithms with data from biomass
767 burning and ambient measurements. It is unclear how the algorithms will work for other absorbing
768 aerosols (e.g., dominated by fossil fuel emissions or mineral dust). Further evaluation of the
769 performance of the new algorithm on other aerosol sources may help to address this issue.
770 Regardless, we argue that our approach can standardize reported absorption coefficients at long-
771 term monitoring sites, which has the potential to yield a better data set with which to evaluate
772 chemistry-climate models.

773 **Code and data availability.** The code for the algorithm was initially written in Igor Pro
774 (WaveMetrics Inc.) and has been developed to be accessible through either Python (Version 3.7.5)
775 or Igor Pro. The implementation of our algorithm is available at
776 <https://doi.org/10.5281/zenodo.3742342>. The FIREX aerosol products are available at
777 <https://esrl.noaa.gov/csd/project/firex>. The SGP aerosol products are available at
778 <https://www.archive.arm.gov/discovery/> (February 2013–July 2013, 36° 36' 18.0" N, 97° 29' 6.0"
779 W: Southern Great Plains Central Facility, data set accessed 01/16/19).

780 **Author contributions.** HL developed the model, conducted the evaluations, and drafted the
781 manuscript. AAM and GRM edited the manuscript and obtained funding.

782 **Competing interests.** The authors declare that they have no conflict of interest.

783 **Acknowledgements.** The authors would like to thank Allison Aiken (Los Alamos National
784 Laboratory) for useful discussions regarding the SGP PASS-3 data. The authors greatly
785 acknowledge Vanessa Selimovic, and Robert Yokelson from University of Montana for lending
786 us the PAX-405; Patrick Sheridan, John Ogren, and Derek Hageman from NOAA for lending us
787 the CLAP; and Anthony Prenni from the National Park Service for lending us the AETH during
788 the FIREX campaign. We also thank Nick Good (Colorado State University), Jim Roberts (NOAA)
789 and Carsten Warneke (NOAA) for their on-site support at FSL.

790 **Financial support.** The authors and FIREX data were supported by NOAA Climate Program
791 Office Grant NA16OAR4310109. The ambient data at SGP site in Lamont (OK, USA) were
792 obtained from the atmospheric radiation measurement (ARM) user facility, a U.S. Department of
793 Energy (DOE) Office of Science user facility managed by the Office of Biological and
794 Environmental Research.

795 **Review statement.** The authors thank Associate Editor Paolo Laj for handling this submission and
796 the anonymous reviewers for their valuable comments.
