

Figure S1. An example of a calibration using the indirect FAGE technique for CH₃O₂ detection using 184.9 nm photolysis of water vapour at 295 K and atmospheric pressure to generate OH radicals. CH₃O₂ radicals were generated using the reaction OH with CH₄ in the presence of O₂, in the range of ~ $(0.5-2.0) \times 10^{10}$ molecule cm⁻³ by varying the power supplied to the photolysis lamp; [CH₄] = 5.0×10^{16} molecule cm⁻³ and [NO] = 6.7×10^{13} molecule cm⁻³. A line of best fit through these data yields a sensitivity factor $C_{\text{CH3O2}} = (7.8 \pm 0.4) \times 10^{-10}$ counts cm³ molecules⁻¹ s⁻¹ mW⁻¹, where the error limits are the standard error of the fit to the data. The error limits in the FAGE signal are statistical errors at the 1σ level.

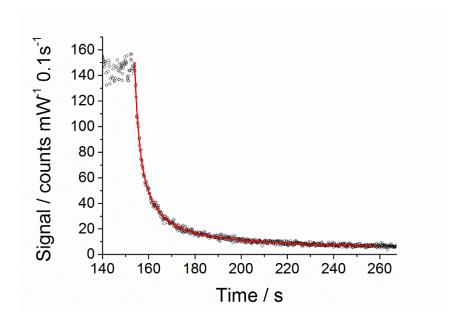

Figure S2. CH₃O₂ decay via its self-reaction measured by FAGE for the 80 mbar He:O₂ (3:1) atmosphere within HIRAC. Radicals were generated by photolysis of molecular chlorine in the presence of methane, with $[Cl_2] = 3.2 \times 10^{14}$ molecule cm⁻³ and $[CH_4] = 2.5 \times 10^{17}$ molecule cm⁻³. The photolysis lamps were turned off at ~150 s. Fitting Eq. (5) in the main text to the data yields the sensitivity factor $C_{\text{CH}3O2} = (3.89 \pm 0.05) \times 10^{-9}$ counts cm³ molecules⁻¹ s⁻¹ mW⁻¹. The error limits are statistical errors at the 1σ level.

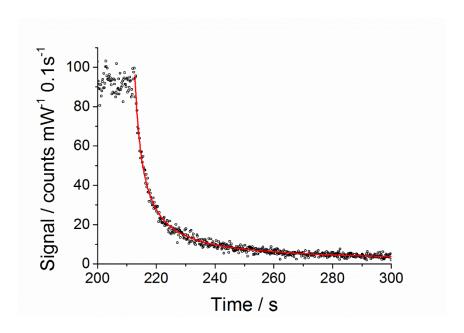

Figure S3. CH₃O₂ decay via its self-reaction measured by FAGE for the 100 mbar synthetic air atmosphere within HIRAC. Radicals were generated by photolysis of molecular chlorine in the presence of methane, with [Cl₂] = 3.3×10^{14} molecule cm⁻³ and [CH₄] = 2.5×10^{17} molecule cm⁻³. The photolysis lamps were turned off at ~210 s. Fitting Eq. (5) in the main text to the data yields the sensitivity factor $C_{\text{CH3O2}} = (2.65 \pm 0.04) \times 10^{-9}$ counts cm³ molecules⁻¹ s⁻¹ mW⁻¹. The error limits are statistical errors at the 1σ level.

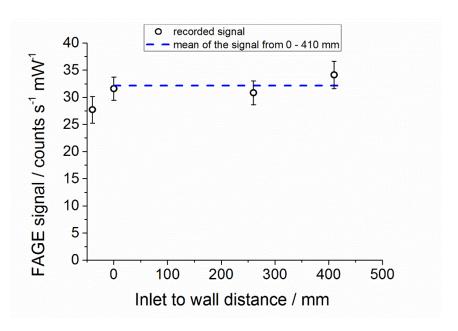

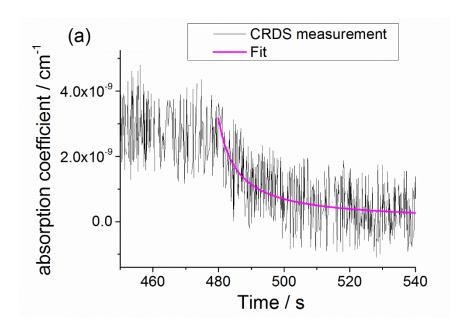

Figure S4. Measurement of the CH₃O₂ radical signal plotted against the distance the FAGE inlet protrudes from the HIRAC chamber. Each point (black circles) shows the steady-state CH₃O₂ signal averaged over 5 min for a certain position of the instrument inlet across the chamber radius. The blue line represents the mean of the signal recorded from 0 mm (inlet flush with the wall) to 410 mm inlet to internal wall distance. CH₃O₂ was generated by $(\sim 2.5 \times 10^{13} \text{ molecule cm}^{-3})$ in photolysing ozone the presence methane $(2.5 \times 10^{17} \text{ molecule cm}^{-3})$ at 254 nm. The FAGE instrument couples to the chamber through a flange mounted on the outside, allowing the inlet to be positioned behind the chamber walls similar to the CRDS mirrors. Here (40 mm behind the wall, so -40 mm), a 14% signal drop was observed compared to the mean of values from 0-410 mm.

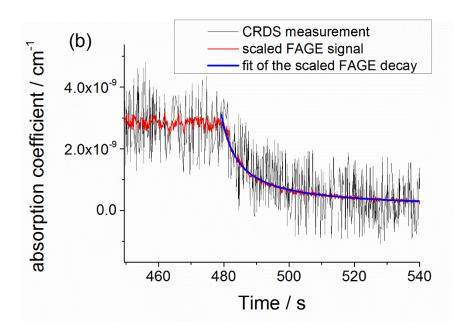

Figure S5. Second—order decay of the CH₃O₂ absorption coefficient at 7488 cm⁻¹ from CRDS data (single ring-down events – black line in both panels (a) and (b)) along with the FAGE signal monitored simultaneously but scaled vertically to overlap the CRDS data (red line; panel (b)). The traces were recorded at 295 K and with a 80 mbar mixture of He:O₂ = 3:1; $[Cl_2]_0 = 1.1 \times 10^{14}$ molecule cm⁻³ and $[CH_4]_0 = 2.5 \times 10^{16}$ molecule cm⁻³. The fit of Eq. (8) in the main text to the CRDS data (magenta line in panel (a)) resulted in $\sigma_{HO^2} = (1.71 \pm 0.15) \times 10^{-20}$ cm² molecule⁻¹ while the fit of the same equation to the scaled FAGE data (blue line; panel (b)) gave $\sigma_{HO^2} = (1.55 \pm 0.02) \times 10^{-20}$ cm² molecule⁻¹. The error limits are statistical errors at the 1σ level.

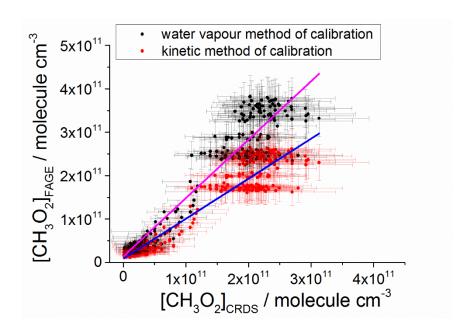

Figure S6. Correlation plots of the data generated by using FAGE and CRDS at 1000 mbar of air. [CH₃O₂] measured by FAGE is plotted against [CH₃O₂] measured by CRDS. [CH₃O₂]_{CRDS} was calculated using a cross section of 1.49×10^{-20} cm² molecule⁻¹. FAGE was calibrated by two methods described in the main text: the 184.9 nm photolysis of water vapour in the presence of CH₄/O₂ (black circles, $C_{\text{CH}_3\text{O}_2} = (8.03 \pm 1.37) \times 10^{-10}$ counts cm³ molecules⁻¹ s⁻¹ mW⁻¹) and using the second order kinetics of the CH₃O₂ temporal decay (red circles, $C_{\text{CH}_3\text{O}_2} = (1.16 \pm 0.15) \times 10^{-9}$ counts cm³ molecule⁻¹ s⁻¹ mW⁻¹). The separate linear fits to the data obtained using the two FAGE calibration methods result in a gradient of 1.35 ± 0.07 and an intercept of $(1.4 \pm 0.3) \times 10^{10}$ molecule cm⁻³ for the data using the water vapour calibration and a gradient of 0.92 ± 0.05 and an intercept of $(8.8 \pm 2.3) \times 10^9$ molecule cm⁻³ for the data using the kinetic method of calibration. The linear fits were generated using the orthogonal distance regression algorithm; fit errors at 2σ level. Each point is an averaged value over 5 s.
