

We greatly value the careful reading and the detailed comments provided by the referees. The responses to the comments of the referees in our direct reply (shown below) and within the revised manuscript (see marked copy) are provided below. The pages and lines indicated below correspond to those in the marked copy.

### **Response to RC1 (Referees' comments are italicized)**

**1. Referee comment:** *"... the authors describe how to apply a commercially available krypton lamp that emits two Kr lines in the VUV at 123.582 nm (10.030 eV) and 116.486 nm (10.641 eV)." "Line 17: the light, which is emitted are atomic lines as mentioned above and not wavelength bands as written by the authors. The right values for these lines are given above."*

#### **Author response:**

We have modified the texts as suggested. However, we note that the emission lines from krypton lamps exhibit significant pressure broadening.

**Page 1 line 16: "The VUV-IS utilizes a compact krypton lamp that emits light at two wavelengths corresponding to energies of ~10.030 and 10.641 eV."**

**2. Referee comment:** *"The description of figure 3 and figure 5 is sometimes a little confusing. This should be improved. Maybe the authors could indicate figure 3 a,b,c,d and 5 a,b,c,d instead of saying "upper left" and "lower left". "*

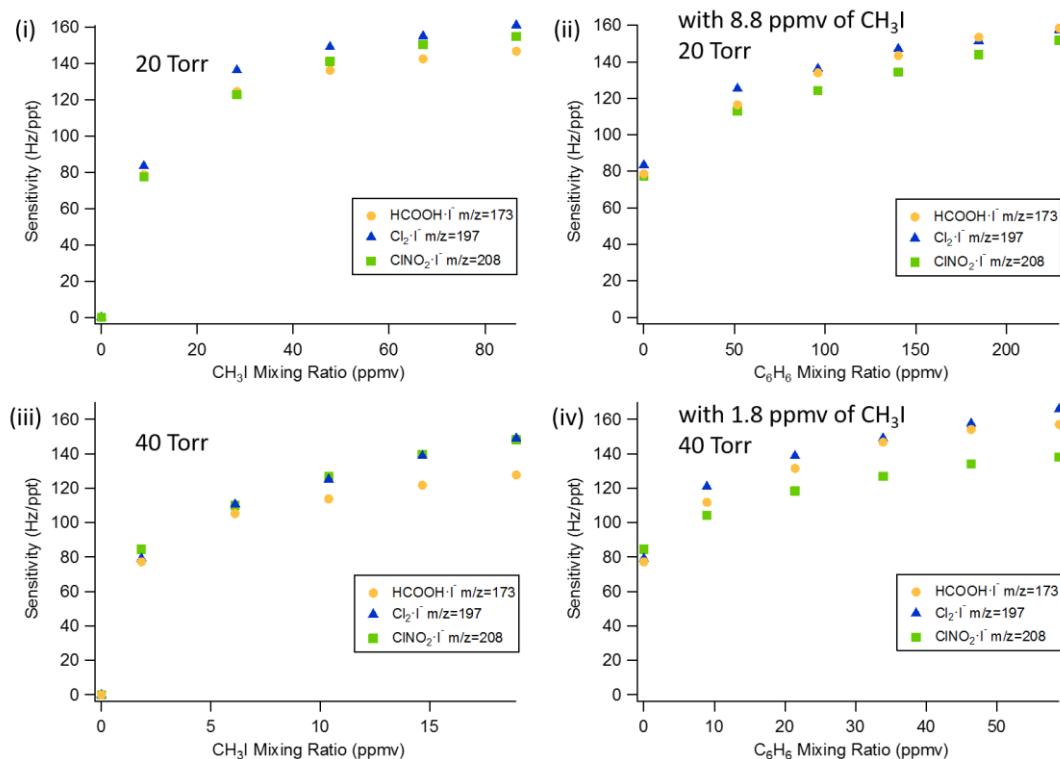

#### **Author response:**

We modified Figure 3 and 5 (Figure 4 and 3 in revised manuscript, respectively) "upper left" etc to i, ii, iii, iv, to avoid confusions with VUV-IS configuration (a) and (b).

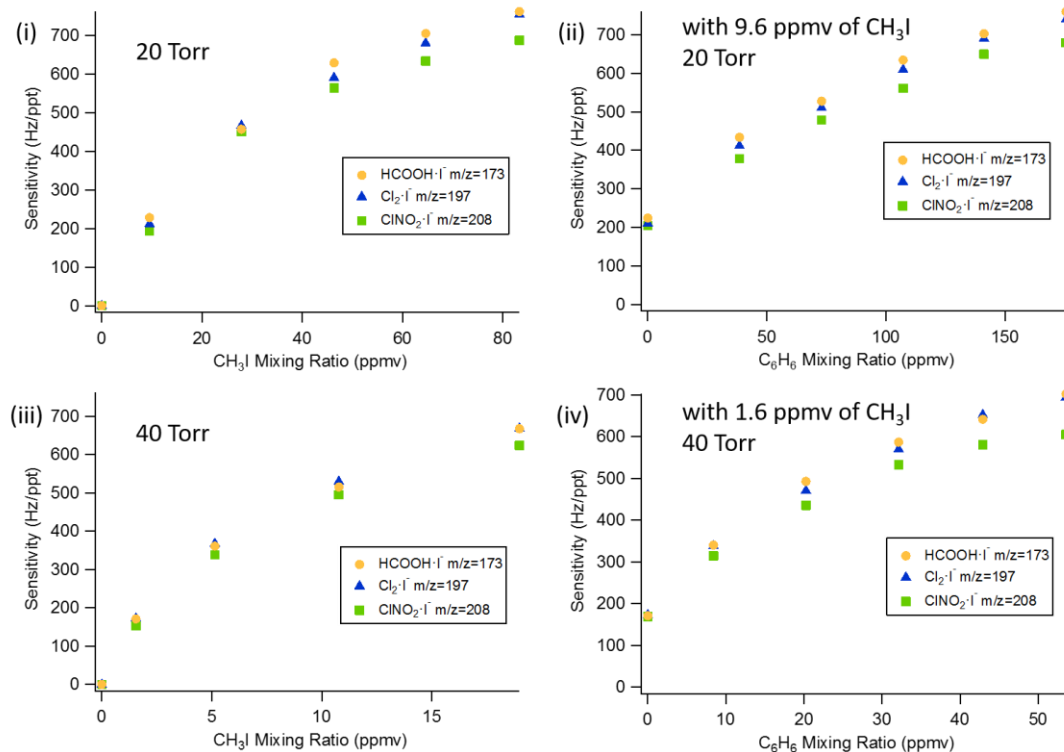

**3. Referee comment:** *"At line 176 the authors write: "At 40 Torr, up to 58.9 ppmv C6H6 was added to 1.8 ppmv of CH3I to reach the maximum level of sensitivities (157, 166, and 138 Hz pptv-1 for formic acid, Cl2 and ClNO2, respectively) when using 19.0 ppmv of CH3I." I suspect the 58.9 ppmv should be exchanged by 19 ppmv as shown in the lower left part of figure 5. Also in Table 1 this should be corrected: Instead of 0-58.9 it should be written 0-19, I guess. It would also be easier for the reader to follow, when in figure 3 upper left would be written in the graph: 9.6 ppmv CH3I, in the lower left 1.6 ppmv CH3I, in figure 5 upper left: 8.8 ppmv CH3I and lower left : 1.8 ppmv CH3I. In the figure caption the same values like in the text should be used: 110 ppmv and 8.8ppmv."*

#### **Author response:**

The text in line 176 (line 187 in revised manuscript) and Table 1 were both correct (58.9 ppmv of benzene was used here). The lower left panel (iv) of Figure 5 (Figure 3 in revised manuscript) was modified to the correct plot. The amount of CH<sub>3</sub>I used was provided on the figures and captions as suggested.

**Figure 3. Q-CIMS using VUV-IS configuration (b): (i) sensitivity as a function of CH<sub>3</sub>I at 20 Torr. (ii) sensitivity as a function of C<sub>6</sub>H<sub>6</sub> at 20 Torr with 8.8 ppmv of CH<sub>3</sub>I. (iii) sensitivity as a function of CH<sub>3</sub>I at 40 Torr. (iv) sensitivity as a function of C<sub>6</sub>H<sub>6</sub> at 40 Torr with 1.8 ppmv of CH<sub>3</sub>I.**

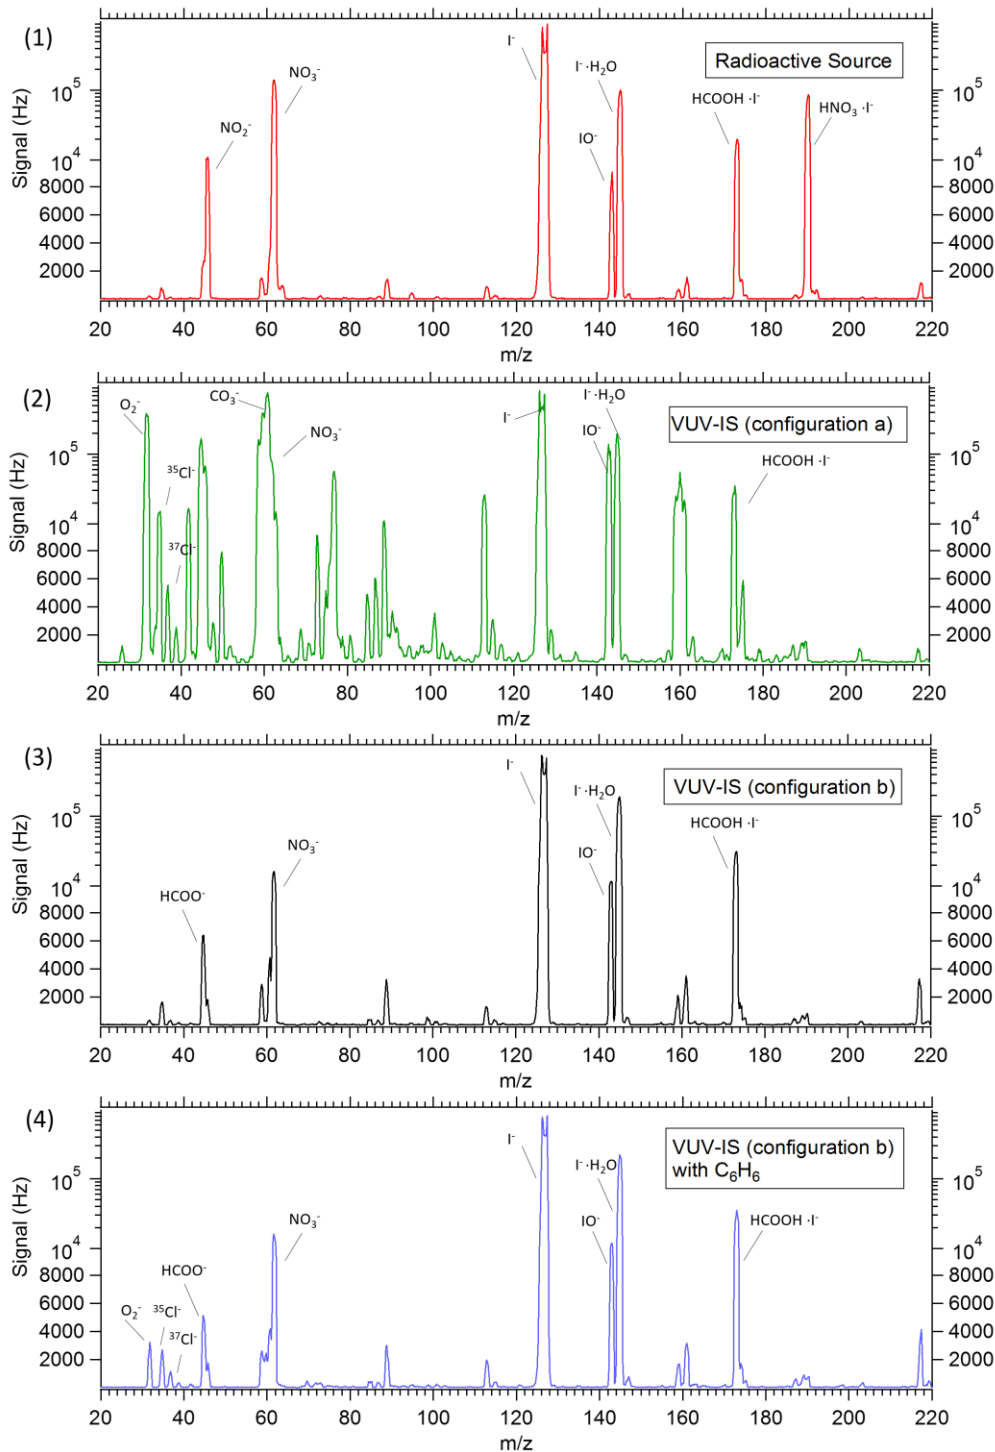

**Figure 4. Q-CIMS using VUV-IS configuration (a): (i) sensitivity as a function of CH<sub>3</sub>I at 20 Torr. (ii) sensitivity as a function of C<sub>6</sub>H<sub>6</sub> at 20 Torr with 9.6 ppmv of CH<sub>3</sub>I. (iii) sensitivity as a function of CH<sub>3</sub>I at 40 Torr. (iv) sensitivity as a function of C<sub>6</sub>H<sub>6</sub> at 40 Torr with 1.6 ppmv of CH<sub>3</sub>I.**

**4. Referee comment:** “It would also be good for the reader to indicate some masses of the spectra like it is explained in the text.”

**Author response:**

We have modified Figure 5 and 8 as suggested.

**Figure 5.** Mass spectra of ambient air from a Q-CIMS with (1) a standard radioactive ion source, (2) VUV-IS in configuration (a), (3) VUV-IS in configuration (b), and (4) VUV-IS in configuration (b) with ~100 ppmv of  $\text{C}_6\text{H}_6$  and ~10 ppmv of  $\text{CH}_3\text{I}$ . Note that the  $\text{I}^-$  signal is saturated in all mass spectra.

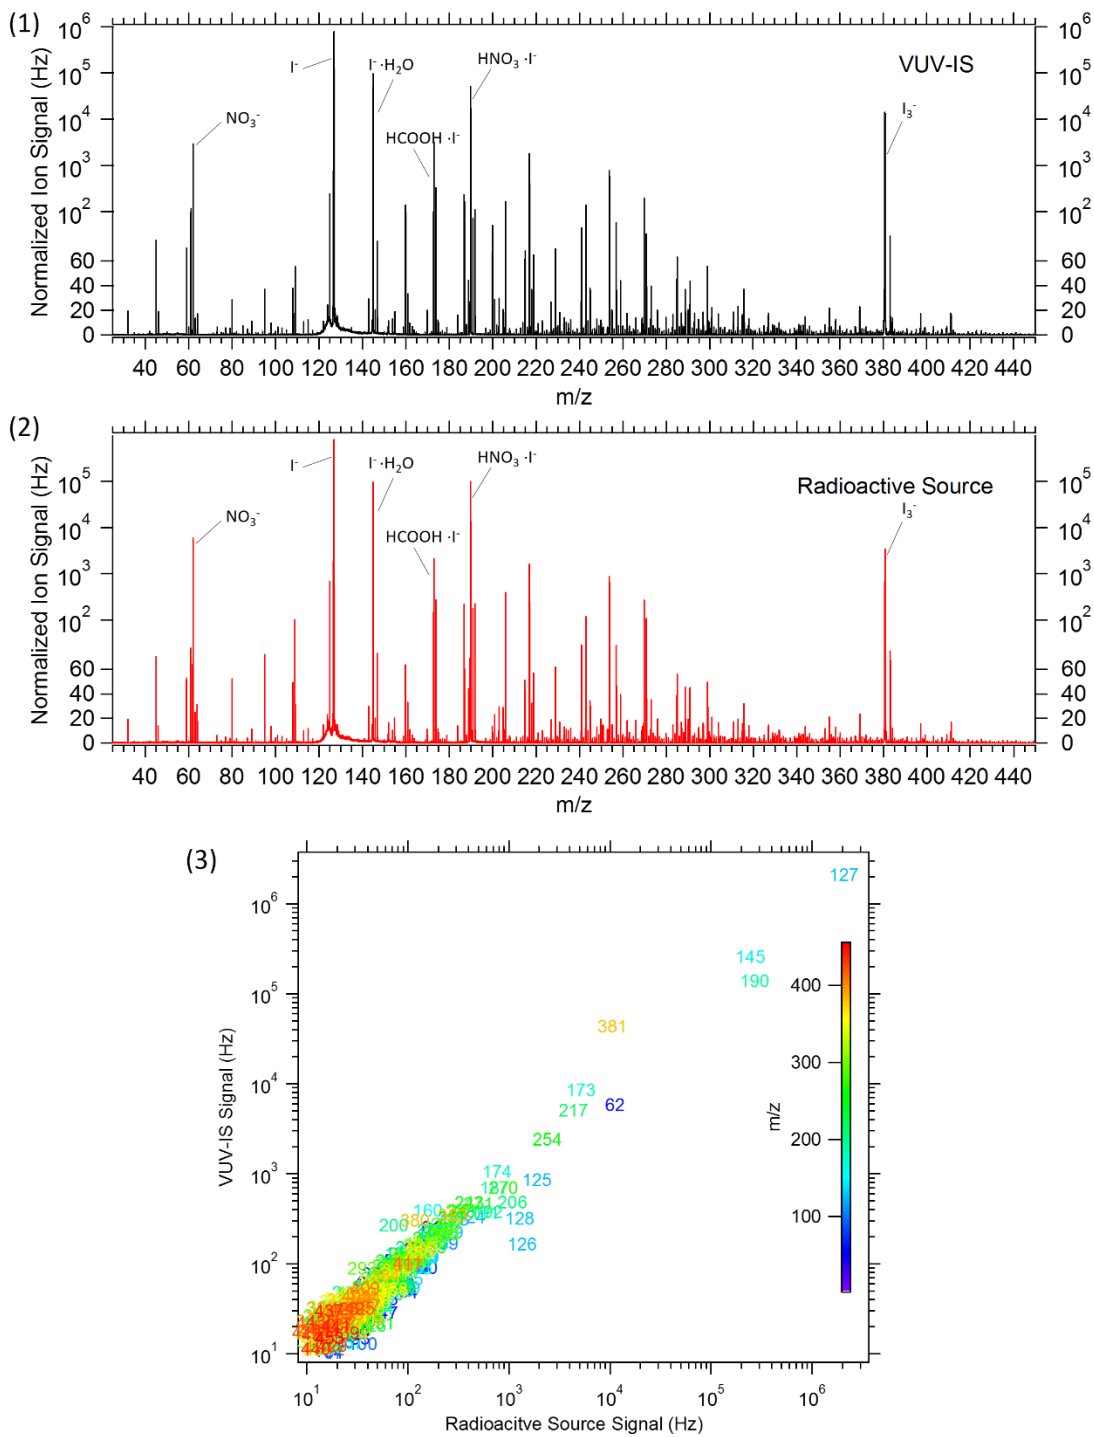

Figure 8. Mass spectra of ambient air in Boulder, CO from a TOF-CIMS with (1) a VUV-IS (2) a radioactive source. The bottom panel (3) is a correlation plot of the individual mass signals with the VUV-IS versus those obtained with a radioactive source, with each ion labeled by its nominal mass.

5. Referee comment: “The authors used two configurations to show that configuration a generates many additional ions compared to a radioactive source. The explanation is that these

*ions might be created by the VUV radiation. Do the authors see all these additional ions also when they do not use any methyl iodine or benzene?"*

**Author response:**

Yes we did tests without CH<sub>3</sub>I or benzene, and additional peaks (e.g. Cl<sup>-</sup>, O<sub>2</sub><sup>-</sup> and masses associated with O<sub>2</sub><sup>-</sup> chemistry) similar to those in Figure 5(2) where observed when using VUV-IS configuration (a). These additional peaks didn't show up when using VUV-IS configuration (b). These tests also indicate the source of the interference peaks are photoelectrons generated on the illuminated surface of the flow tube.

**Response to RC2 (Referees' comments are italicized)**

**6. Referee comment:** *"A general point. I- CIMS was first deployed for measurement of PAN and this method is still widely used. Why was PAN not tested in the lab? It appears from fig. 4 that the signal at 59 amu is much larger when using the VUV (config a) compared to Po210. Is this due to a better sensitivity, a worse background or changing ambient conditions? If the latter is true, it is not clear what this figure hopes to convey. As mentioned below, a spectra obtained in zero-air should be presented in order to assess the potential of the VUV-source properly."*

**Author response:**

We chose to focus on an unheated I-CIMS for this work as this is probably the most common CIMS method used in the community. The PAN detection by TD-CIMS is more specialized, involves a heated inlet, and is not as widely used. The mass spectrum with the VUV source in configuration (a) does have an obvious background at 59 amu as well as other masses. We showed this mass spectrum to demonstrate the issue of stray photoelectrons which would impact many measurements. We also showed simple solutions to minimize this issue. We have added a mass spectrum to the SI (Figure S3) to show that PAN can be detected with TD-CIMS using a VUV-IS. We have also a short section in the results to report the quick tests requested by the reviewer.

**Page 5 line 150:** "

**2.5 TD-CIMS**

**The sensitivity of TD-CIMS with a VUV-IS (Slusher et al., 2004) was also tested for PAN. The configuration of the TD-CIMS system used in this work is almost identical to that described in Lee et al. (2019) with the radioactive source replaced with the VUV-IS in configuration (b). A known amount of PAN was generated using a photolytic source similar to that described by Warneck and Zerbach (1992). A calibration standard of 1 ppbv of PAN was produced by adding the output of the photolytic source to PAN free ambient air. PAN free air was generated by passing ambient air through a QF 40 nipple filled with stainless steel wool heated to 150 °C (Flocke et al., 2005)."**

**Page 9 line 253:** "

**3.6 PAN Measurement Tests**

**Preliminary tests using the Q-CIMS as a TD-CIMS demonstrated the potential of the VUV-IS for use in the measurement of PAN. Mass spectra of ambient air with and without**

PAN are shown in Figure S3. The sensitivity towards PAN was observed to be 49.4 Hz/pptv with an LOD (Signal to noise ratio = 3:1) of 0.64 pptv for a 1 minute integration. No significant interferences were observed during the ambient air tests.”

Figure S3. Mass spectra of zeroed ambient air with and without PAN calibration standard.

**7. Referee comment:** “L23 How does deploying the instrument in the field for a month demonstrate reliability? Section 3.4 and Fig 7 do not really help convince (beyond simply stating that it was operated continuously for a month) that the VUV source can be operated under field conditions. The data (HC(O)OH measurements) are not discussed in terms of their quality or compared to other measurements. Did the primary ion-current (lamp output) change over one month of operation? What does the manufacturer state concerning the operational lifetime (in hours) of the PKS 106?”

#### Author response:

Running the CIMS with a lamp for a month in a remote location does demonstrate reliability but we agree it doesn't demonstrate the quality of the measurement. Our primary goal for this CIMS during the OPECE campaign was to measure halogen containing compounds. However, we found the presence of halogens to be intermittent so we chose to show the formic acid data. Formic acid is routinely measured by I- CIMS and is ubiquitous in the atmosphere as both an emission and a secondary chemical product. So the formic data offers a way to show the CIMS with a lamp could be operated continuously for an extended period.

**Page 8 line 230:** “Formic acid which is routinely measured by I-CIMS and ubiquitous in the atmosphere as both an emission and a secondary chemical product was also monitored

**during the campaign. These observations demonstrate that I-CIMS with a VUV-IS could be operated continuously for an extended period.”**

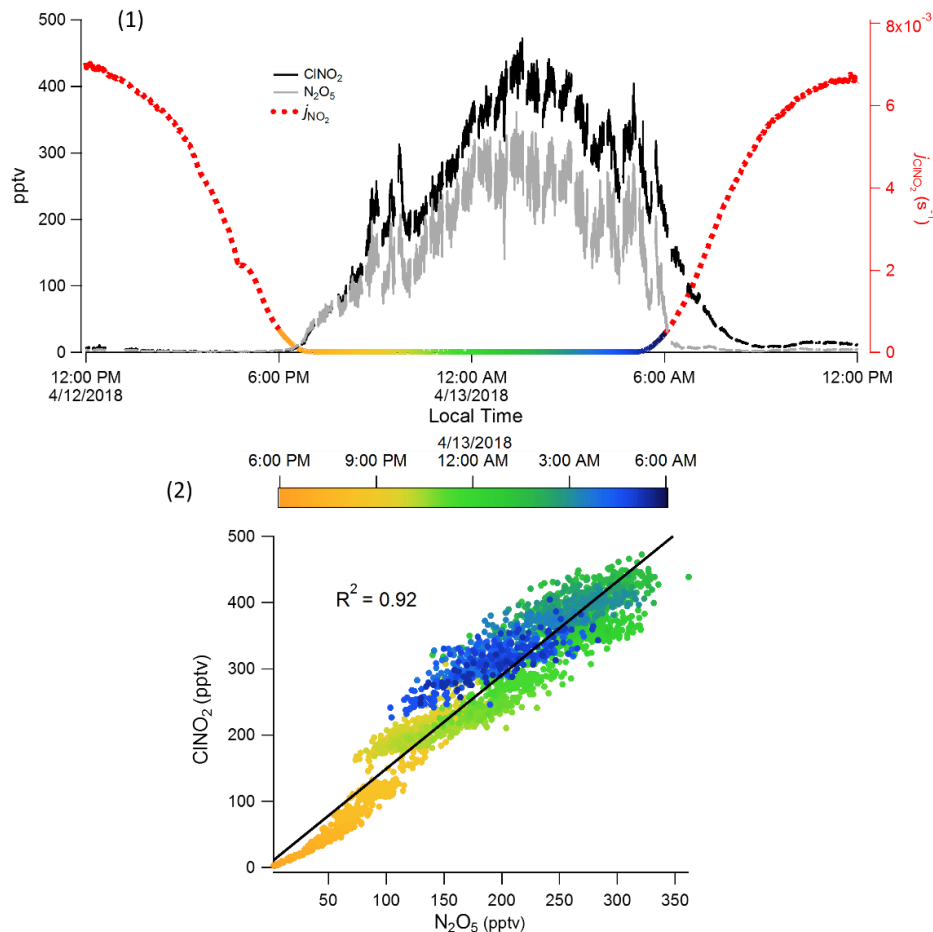

This was one of our major concerns going into the field campaign as we were deploying in an unheated shelter in a remote location in a bird sanctuary in the Yellow River Delta with intermittent power issues. For this reason, we have provided more details of the physical setup and describe the temperature variance experienced by the CIMS.

**Page 7 line 216: “The I-CIMS was deployed in a shelter, with neither heating nor air conditioning, in a remote location in a bird sanctuary in the Yellow River Delta. The site experienced intermittent power interruptions and large ambient temperature variations, from -2.5 to 29.1 °C, with the temperature inside the shelter ranging from ~10 to 40 °C.”**

In order to address the data quality question, we have added a figure with representative observations of ClNO<sub>2</sub> and N<sub>2</sub>O<sub>5</sub> for this site when halogens were observed (Figure 6). This figure is consistent with expected behavior of ClNO<sub>2</sub> and N<sub>2</sub>O<sub>5</sub> as they accumulate during night time and decay after sunrise. This indicates the performance of the CIMS is reasonable.

**Page 8 line 220: “The primary goal for the I-CIMS during the OPECE campaign was to measure halogen containing compounds. However, we found the presence of halogens to be intermittent. Figure 6 shows representative observations of ClNO<sub>2</sub> and N<sub>2</sub>O<sub>5</sub> for this site when halogens were observed. This figure is consistent with the expected behavior of ClNO<sub>2</sub> and N<sub>2</sub>O<sub>5</sub>, both accumulate during night time, and both decrease after sunrise due to photolysis of ClNO<sub>2</sub> and thermal decomposition of N<sub>2</sub>O<sub>5</sub> followed by photolysis of NO<sub>3</sub>. ClNO<sub>2</sub> is a product of reaction between N<sub>2</sub>O<sub>5</sub> and chloride containing aerosol (R1, Finlayson-Pitts et al., 1989), and ClNO<sub>2</sub> and N<sub>2</sub>O<sub>5</sub> are well correlated (R<sup>2</sup> = 0.94, Figure 6(2)) during the night (6 pm, April 12 to 6 am, April 13). These measurements of ClNO<sub>2</sub> and N<sub>2</sub>O<sub>5</sub> indicate the performance of the I-CIMS with the VUV-IS is sufficient to capture atmospheric levels and variability.**

**Figure 6.** Measurements of  $\text{ClNO}_2$  and  $\text{N}_2\text{O}_5$  using I-CIMS with VUV-IS between 12 pm of April 12 and 12 pm of April 13, 2018 during OPECE campaign. (1) time series along with  $j_{\text{NO}_2}$  (to delineate night and day) and (2) a correlation plot of  $\text{ClNO}_2$  concentration versus  $\text{N}_2\text{O}_5$  concentration during the night time (6 pm, April 12 to 6 am, April 13).

The lifetime of this lamp is claimed to be 4000 hours (~5.5 months) by the manufacturer, and we did not observe an obvious degradation of CIMS sensitivity. The CIMS sensitivity to formic acid was measured to be  $185.2 \pm 48.3 \text{ Hz pptv}^{-1}$  during the first 24 hours, and  $180.5 \pm 24.3 \text{ Hz pptv}^{-1}$  during the last 24 hours of the mission. So we did not notice any drop in sensitivity that could be attributed to a decrease in light intensity from the lamp.

**Page 4 line 118:** “The lifetime of this lamp is estimated to be 4000 hours (~5.5 months of continuous use) by the manufacturer.”

**Page 8 line 236:** “Online calibration of formic acid was performed every 30 minutes during the mission. The CIMS sensitivity to formic acid was measured to be  $185.2 \pm 48.3 \text{ Hz pptv}^{-1}$  during the first day, and  $180.5 \pm 24.3 \text{ Hz pptv}^{-1}$  a month later, so we did not notice any drop in sensitivity that could be attributed to a decrease in light intensity from the lamp. In addition, we have used the same VUV-IS since the OPECE field mission (Spring 2018) through early 2020 for both lab studies and field measurements, and have not found obvious sensitivity degradations.”

**Finlayson-Pitts, B. J., Ezell, M. J. & Pitts, J. N.: Formation of chemically active chlorine compounds by reactions of atmospheric NaCl particles with gaseous N<sub>2</sub>O<sub>5</sub> and ClONO<sub>2</sub>. Nature 337, 241–244, 1989.**

**8. Referee comment:** “L26 *The spectrum in ambient air was cleaner. This could mean that the VUV source does not detect everything the Po210 source does. Alternatively, it could imply that the primary ion spectrum is less complex. Please clarify. Again, it would be nice to see a comparison of the primary ion spectra in zero air, at least in the supplement.*”

**Author response:**

Both the VUV and polonium sources produce similar amounts of I<sup>-</sup> as well as other ions. So it is hard to understand why the VUV source does not detect everything in the same manner as the polonium source. They both utilize reactions of I<sup>-</sup> in a flow tube. We can certainly obtain a mass spectra in zero air, although we note that most complications with CIMS come from the presence of ozone and water, but we have trouble accessing our laboratory at this time due to COVID.

**9. Referee comment:** “L34 . . . *used to detect many atmospheric trace gases. . . . But then only BrO and PAN are named. Why not simply list what classes of trace gases have been measured (organic, halogen, nitrates etc)?*”

**Author response:**

We have modified the texts as suggested.

**Page 2 line 33:** “CIMS using the iodide anion (I<sup>-</sup>) and its water clusters as reagent ions (I-CIMS) has been widely used in the measurements of many atmospheric trace gases, e.g. organic and inorganic acids (hydrogen chloride HCl, nitric acid HNO<sub>3</sub>, formic acid HCOOH, etc.), halogens (bromine oxide BrO, nitryl chloride ClONO<sub>2</sub>, etc.) and peroxy-carboxylic nitric anhydrides (PANs) ) (Slusher et al., 2004; Huey, 2007; Phillips et al., 2013; Lee et al., 2014; Liao et al., 2014; Neuman et al., 2016; Liu et al., 2017; Priestley et al., 2018; Bertram et al., 2011; Thornton et al., 2010; Osthoff et al., 2008).”

**10. Referee comment:** “L43 *“little” = “few”?*”

**Author response:**

We have modified the texts as suggested.

**11. Referee comment:** “L60 . . . *which can be attached by CH<sub>3</sub>I. . . = which can attach to CH<sub>3</sub>I. . .?*”

**Author response:**

We have modified the texts as suggested.

**12. Referee comment:** “L78/80 *Benzene has a larger cross-section (than CH<sub>3</sub>I). Please quote the cross-sections (and wavelengths) for benzene and CH<sub>3</sub>I here as well as the ionisation potentials (or refer to a section where they are listed/tabulated)*”

**Author response:**

This values was quoted in line 65.

**Page 3 line 65:** “Benzene (C<sub>6</sub>H<sub>6</sub>) can also serve as a VUV absorber to produce photoelectrons as it has a larger absorption cross section ( $4 \times 10^{-17} \text{ cm}^2 \text{ molecule}^{-1}$ ) and an even lower IP ( $9.24378 \pm 0.00007 \text{ eV}$ ) (Nemeth et al., 1993; Capalbo et al., 2016).”

**13. Referee comment:** “L103 *Some details pertaining to the detection of Cl<sub>2</sub> (a reference to the instrument, total uncertainty, cross-section used etc) would be appropriate here.*”

**Author response:**

We have provided more detailed information and reference in the text.

**Page 4 line 102:** “The Cl<sub>2</sub> permeation tube emission rate was measured by conversion to I<sub>3</sub><sup>-</sup> in aqueous solution, and the resulting I<sub>3</sub><sup>-</sup> was quantified by optical absorption at 352 nm on a spectrophotometer (Finley and Saltzman, 2008). The permeation rates were measured to be  $104.7 \pm 7.8 \text{ ng min}^{-1}$  for formic acid and  $14.8 \pm 1.2 \text{ ng min}^{-1}$  for Cl<sub>2</sub>.”

**Reference:**

Finley, B. D., and Saltzman, E. S.: Observations of Cl-2, Br-2, and I-2 in coastal marine air, *J Geophys Res-Atmos*, 113, 2008.

**14. Referee comment:** “L110 *Was the DC power supply a commercial one (also from Heraeus?)*”

**Author response:**

We have added the model and manufacturer.

**Page 4 line 114:** “The Kr lamp is powered by a 4 W DC power supply (UltraVolt® AA Series High-Voltage Biasing Supplies).”

**15. Referee comment:** “L134 *The terms IMR and flow-tube (eg. In Fig.1) are used interchangeably. Please stick to one. As it is not strictly a “flow-tube” Ion Molecule Reactor might be the better choice.*”

**Author response:**

The terms of IMR is more commonly used when talking about Aerodyne TOF-CIMS, and “flow tube” are more commonly used when talking about quadrupole CIMS, so we prefer to stick to the convention to avoid confusion to readers.

**16. Referee comment:** “L144 *What is special about the photoelectrons generated on the metal surfaces. Explain why they are a problem? (Presumably because they can attach to O<sub>2</sub> in this part of the instrument). On the other hand, could metal surfaces in N<sub>2</sub> / CH<sub>3</sub>I gas provide a useful source of photo-electrons upstream of the IMR?*”

**Author response:**

The photoelectrons generated in the flow tube are exposed to O<sub>2</sub> which electron attaches to make O<sub>2</sub><sup>-</sup> and leads to a series of interfering masses. Our preliminary tests shows that using metal surfaces can produce only about 1% I<sup>-</sup> of that achieved with using a gas phase absorber (CH<sub>3</sub>I or C<sub>6</sub>H<sub>6</sub>).

**17. Referee comment:** *“Section 3, Results. The first paragraph in the results section summarises all of the results and introduces all of the Figures from the laboratory tests. As the same conclusions are made in the individual sections that follow (but with the underlying data to support them) this paragraph is redundant. I suggest it can be removed and integrated with the conclusions.”*

**Author response:**

Good comment – We have moved this to the end of the paper and used as the first paragraph of a summary and conclusion section.

**18. Referee comment:** *“L158 Are the mixing ratios of CH<sub>3</sub>I those in the ion-source-flow or in the IMR (after dilution)? Please make this clear throughout the manuscript.”*

**Author response:**

All the mixing ratios of CH<sub>3</sub>I and benzene in the manuscripts are those in the ion source flow. We mentioned this in line 145 for TOF-CIMS and line 167, 208 for Q-CIMS. We have also clarified it in line 137.

**Page 5 line 137: “Mixing ratios of CH<sub>3</sub>I and C<sub>6</sub>H<sub>6</sub> mentioned in the following sections are the mixing ratios in the total ion source flow (1 or 1.2 slpm).”**

**19. Referee comment:** *“L199 I’m surprised that the authors did not add SF<sub>6</sub> to test the potential of extension to the use of the VUV-IS. This would have been a very simple experiment. I would encourage the authors to do this “10 minute experiment” and add the qualitative observation (formation of SF<sub>6</sub><sup>-</sup> ?) to this manuscript.”*

**Author response:**

We are working on using SF<sub>6</sub><sup>-</sup> with the lamp. This is really not a “10 minute experiment”, because SF<sub>6</sub><sup>-</sup> chemistry is more complicated than I<sup>-</sup> chemistry. E.g. its reaction with water vapor and O<sub>3</sub> are troublesome to both its selectivity and stability, so we have to minimize the reaction time and number density in the flow tube. So we don’t have extensive or conclusive results at this time. We have added a figure (S4) that shows preliminary measurements of formic and acetic acid using an SF<sub>6</sub><sup>-</sup> during test flights.

**Page 6 line 157: “**

**2.6 SF<sub>6</sub><sup>-</sup>-CIMS**

**The instrument used to test the VUV-IS with SF<sub>6</sub><sup>-</sup> as a reagent ion is nearly identical to that used previously to measure BrO on the NCAR GV research aircraft (Chen et al., 2016). The operating parameters of the instrument are very similar to those used**

previously to simultaneously detect sulfur dioxide, formic, and acetic acid (Nah et al., 2018). However, in this application the radioactive ion source was replaced with a VUV-IS in configuration (b). The system was periodically calibrated in flight by adding a known amount of isotopically labeled  $^{34}\text{SO}_2$  into the sampled air flow.”

Page 9 line 258: “

### 3.7 SF<sub>6</sub>-Q-CIMS Tests

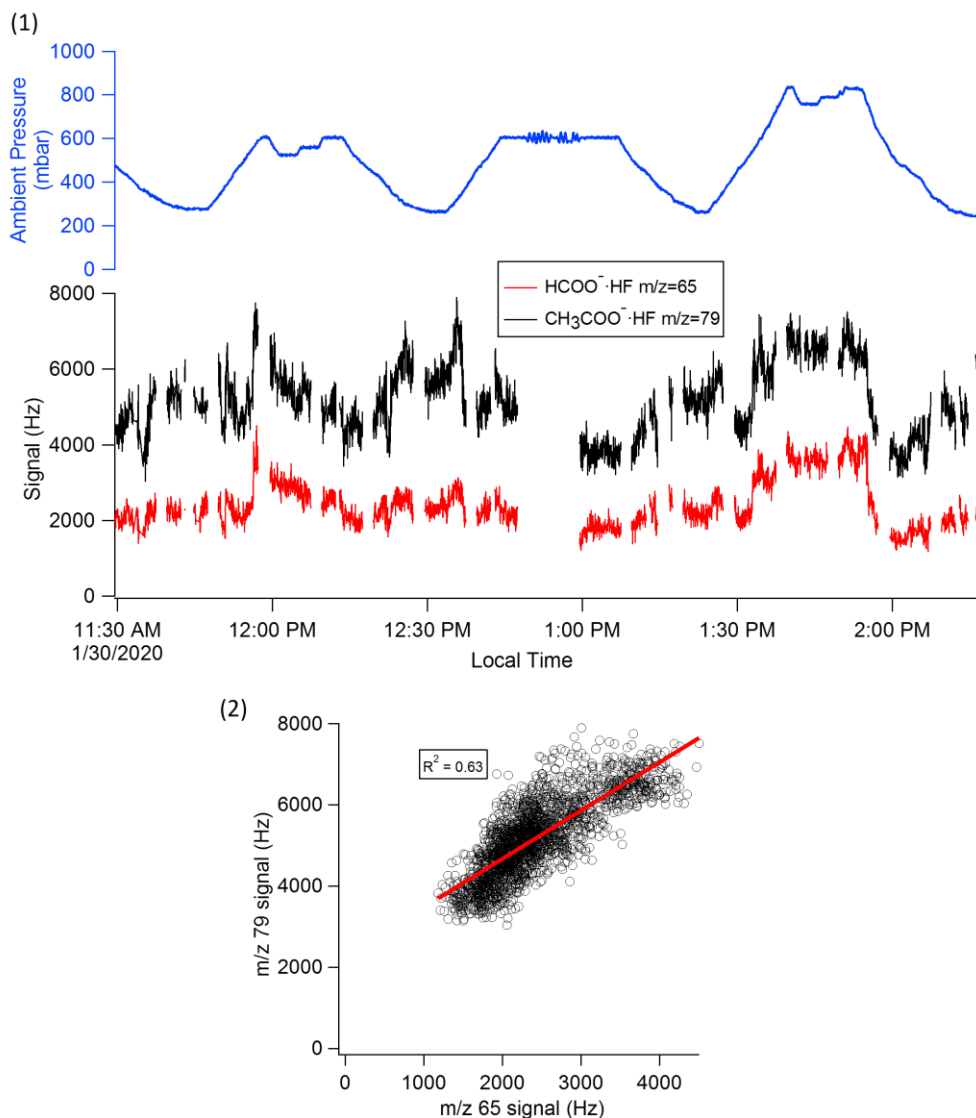

Preliminary aircraft-based measurements of sulphur dioxide, formic and acetic acid using the SF<sub>6</sub>-CIMS with the VUV-IS were conducted during an Asian Summer Monsoon Chemical and Climate Impact Project (ACCLIP) test flight based out of Broomfield, Colorado on January 30, 2020. Time series of formic and acetic acid signals are shown in Figure S4(1). The signals of formic and acetic acid are correlated ( $R^2 = 0.63$ , Figure S4(2)) as observed in previous studies (Souza and Carvalho, 2001; Paulot et al., 2011; Nah et al., 2018). We did not perform online calibrations for formic or acetic acid. Sensitivities to formic and acetic acids during this test flight are estimated to be 5-20 Hz/ppTV based on online calibrations of  $^{34}\text{SO}_2$  and measurements of the ratio of their sensitivities (Nah et al., 2018).”

**Figure S4.** (1) Time series of formic acid signal (HCOO<sup>-</sup>·HF, m/z 65, red line), acetic acid signal (CH<sub>3</sub>COO<sup>-</sup>·HF, m/z 79, black line), and ambient pressure (blue line). (2) A correlation plot of the CH<sub>3</sub>COO<sup>-</sup>·HF signal (m/z 79) versus HCOO<sup>-</sup>·HF signal (m/z 65). Data was taken from the NCAR GV during a test flight based out of Broomfield, CO using a VUV-IS.

**20. Referee comment:** “Are other lamps available (different noble gases and emission energies) to extend the use of photo-ionisation sources to generate other primary ions for CIMS. Or, put another why, why choose a Krypton line?”

**Author response:**

Photoionization detector lamps (PID) are available with a variety of gas fills including argon, krypton and xenon gas. However xenon’s photon energy (9.6 eV) is lower than krypton (10 and 10.6 eV). The argon lamp has a higher photo energy (11.8 eV) but it also lithium fluoride (LiF) as a window material which is hygroscopic. The krypton lamp uses a magnesium Fluoride (MgF<sub>2</sub>) window which is less hygroscopic.

**21. Referee comment:** “L200 “electron attaching compounds” = trace gases with large electron affinities?”

**Author response:**

Electron attaching compound are molecules like O<sub>2</sub>, SF<sub>6</sub>, CH<sub>3</sub>I that attach electrons to make species such as O<sub>2</sub><sup>-</sup>, SF<sub>6</sub><sup>-</sup>, I<sup>-</sup>. However, SF<sub>6</sub> and O<sub>2</sub> don't have particularly large electron affinities and the electron affinity of CH<sub>3</sub>I is a more difficult concept as it dissociative attaches to form I<sup>-</sup>, so we prefer electron attaching compounds,

**22. Referee comment:** “Section 3.4 I'm not sure what this section seeks to achieve. The information that the lamp can be used for 18 months without degradation of the signal is important but was not gleaned from a 1 month campaign and is lost in this section. I suggest adding this information to the methods section, perhaps with manufactures data about the lifetime of the lamp. Also “no obvious degradation of signal” could be presented in a more quantitative manner. What “signal” is referred to here? What information (Fig. 7) do the J-NO<sub>2</sub> values convey? Seeing that there is no discussion of the data, th J-values simply delineate night and day. But what does that tell us? Why were HC(O)OH mixing ratios chosen to illustrate that the ion-source worked ? Was nothing else measured? Why do the formic acid mixing ratios maximise at nighttime (expected?). I recommend removing this section completely unless significantly more use is made of the field data (a comparison with another instrument would e.g. have been useful).”

**Author response:**

We have been using the same VUV-IS since the OPECE field mission (Spring 2018) till 2020 for both lab studies and field measurements, and we have not find significant degradation of CIMS sensitivity. As mentioned in our response to comment 7, the krypton lamp's lifetime is expected to ~5.5 month of continuous use.

Yes the JNO<sub>2</sub> is to simply delineate night and day. As mentioned above, Figure 7 is to show that the VUV-IS was operated continuously for a month. We are choosing formic acid because it is ubiquitous and easy to measure and calibrate. We are not claiming anything about the quality of the formic acid measurements. As discussed in our response to comment 7, we also presented our measurements on ClNO<sub>2</sub> and N<sub>2</sub>O<sub>5</sub> as a support of our data quality (Figure 6).

**23. Referee comment:** “Section 4. The “discussion” is weak. I suggest taking this text and combining it with the (weak) “conclusions” text to generate a section “discussion of results and conclusions” or something like that.”

**Author response:**

We have modified the text by moving the intro paragraph to an end summary and conclusion sections. We also feel that we have made a strong conclusion – The VUV lamp can eliminate the use of radioactivity for CIMS.

**24. Referee comment:** “L255 Extend the conclusions by taking the first paragraph of text from the results section.”

**Author response:**

We have moved the summary paragraph to the conclusion and make it a “summary and conclusion section”.

**25. Referee comment:** “Fig 4 (1) and (3). It would be good to add the ions to the figures. The  $\text{HNO}_3\text{I}^-$  ion at 1190 amu is the main difference between the Po210 and VUV ion sources and this would be nicely highlighted if the ion-peaks were labelled. In this context, what is the ion at ~144 amu (next to I-H<sub>2</sub>O)? and at ~170 amu?”

**Author response:**

We have added labels to the larger signal ions in the spectra. Please refer to Figure 5 and 8 above in our response to comment 4. There is no peak at 144 but there is a small peak at 143 amu that corresponds to  $\text{IO}^-$ . The peak at ~170 corresponds to  $\text{HCOOH}\cdot\text{I}^-$  at m/z 173.

**26. Referee comment:** “SI: The cross-section of CH<sub>3</sub>I is x 10<sup>-17</sup> (not e17). Give a citation for the cross-section.”

**Author response:**

We have modified the texts as suggested.

**The following are additional minor changes the authors have made to the manuscript:**

1. We corrected the name of one affiliation.

Page 1 line 7: “<sup>2</sup>NOAA Chemical Science Laboratory, Boulder, Colorado, USA, 80305”

2. We added one new reference for TOF-CIMS

Page 5 line 140: “The VUV-IS was also characterized by operation on a commercial TOF-CIMS (Aerodyne Research Incorporated) (Lee et al., 2014; Veres et al., 2020).”

**Abstract.** A new ion source (IS) utilizing vacuum ultraviolet (VUV) light is developed and characterized for use with iodide-  
15 chemical ionization mass spectrometers (I-CIMS). The VUV-IS utilizes a compact krypton lamp that emits light ~~in~~ at two  
~~wavelength bands~~ wavelengths corresponding to energies of ~~~10.0030~~ and ~~10.6641~~ eV. The VUV light photoionizes either  
methyl iodide (ionization potential, IP = 9.54 ± 0.02 eV) or benzene (IP = 9.24378 ± 0.00007 eV) to form cations and  
photoelectrons. The electrons react with methyl iodide to form I<sup>-</sup> which serves as the reagent ion for the CIMS. The VUV-IS  
is characterized by measuring the sensitivity of a quadrupole CIMS (Q-CIMS) to formic acid, molecular chlorine, and nitril  
20 chloride under a variety of flow and pressure conditions. The sensitivity of the Q-CIMS, with the VUV-IS, reached up to ~700  
Hz pptv<sup>-1</sup>, with detection limits of less than 1 pptv for a one minute integration period. The reliability of the Q-CIMS with a  
VUV-IS is demonstrated with data from a month long ground-based field campaign. The VUV-IS is further tested by operation  
on a high resolution time-of-flight CIMS (TOF-CIMS). Sensitivities greater than 25 Hz pptv<sup>-1</sup> were obtained for formic acid  
and molecular chlorine, which were similar to that obtained with a radioactive source. In addition, the mass spectra from  
25 sampling ambient air was cleaner with the VUV-IS on the TOF-CIMS compared to measurements using a radioactive source.  
These results demonstrate that the VUV lamp is a viable substitute for radioactive ion sources on I-CIMS systems for most  
applications. In addition, initial tests demonstrate that the VUV-IS can ~~likely~~ be extended to other reagent ions, ~~such as SF<sub>6</sub><sup>-</sup>~~  
~~which are formed from high IP electron attachers,~~ by the use of VUV absorbers ~~such as benzene~~ with low IPs to serve as a  
source of photoelectrons- for high IP electron attachers, such as SF<sub>6</sub><sup>-</sup>.

## 30 **1. Introduction**

Chemical ionization mass spectrometry (CIMS) has been widely used as a powerful tool to measure various atmospheric compounds with high sensitivity and fast time response. CIMS measurements are based on selective ionization of compounds in air by reagent ions via ion molecule reactions. CIMS using the iodide anion ( $I^-$ ) and its water clusters as reagent ions (I-CIMS) has been widely used in the measurements of many atmospheric trace gases, e.g. ~~bromine oxide (BrO) and peroxyacetyl nitric anhydride (PAN)~~organic and inorganic acids (hydrogen chloride HCl, nitric acid HNO<sub>3</sub>, formic acid HCOOH, etc.), halogens (bromine oxide BrO, nitryl chloride ClNO<sub>2</sub>, etc.) and peroxy-carboxylic nitric anhydrides (PANs) (Slusher et al., 2004; Huey, 2007; Phillips et al., 2013; Lee et al., 2014; Liao et al., 2014; Neuman et al., 2016; Liu et al., 2017; Priestley et al., 2018; Bertram et al., 2011; Thornton et al., 2010; Osthoff et al., 2008).

40 Typically, I-CIMS systems use a radioactive isotope, usually <sup>210</sup>Po, as an ion source. <sup>210</sup>Po emits  $\alpha$  particles (with an energy of  $\sim 5$  MeV) that directly ionize the carrier gas in the ion source to produce secondary electrons. The secondary electrons are thermalized by collisions and react with methyl iodide (CH<sub>3</sub>I) to form  $I^-$  by dissociative electron attachment. The use of radioactive ion sources with the I-CIMS system is well-established and has several important advantages. For example, radioactive sources are exceedingly reliable and are easy to use, as they require no external power. Radioactive sources often  
45 produce relatively clean mass spectra with ~~little few~~ interfering masses. However, radioactive sources have several disadvantages as well. <sup>210</sup>Po is toxic and is highly regulated which often makes it difficult to transport, store, and use in remote locations. We have recently developed a lower activity <sup>210</sup>Po ion source that is subject to fewer regulatory restrictions (Lee et al., 2019). However, there remain applications where the use of any radioactivity is very difficult or prohibited. A more subtle disadvantage is that radioactive ion sources emit continuously, which can lead to the build-up of interfering species. For these  
50 reasons, it is desirable to find a non-radioactive alternative to efficiently generate  $I^-$  and other reagent ions. Electrical discharges and x-ray ion sources have been used as ion sources in atmospheric pressure chemical ionization mass spectrometers (AP-CIMS) (Jost et al., 2003; Skalny et al., 2007; Kurten et al., 2011; Wang et al., 2017). However, they have not been commonly employed with I-CIMS systems perhaps due to limited sensitivity and the generation of interfering ions. Recently Eger et al. (2019) developed a promising ion source using a radio frequency (RF) discharge on an I-CIMS system, providing another  
55 alternative to radioactive sources albeit with lower signal levels. However, the RF source also generated high levels of other ions such as dicyanoiodate anion  $I(CN)_2^-$ , ~~providing which can lead to interference but also provide~~ additional pathways for detecting species such as SO<sub>2</sub> and HCl.

In this work, we investigate the use of a small krypton (Kr) lamp as a substitute for a radioactive ion source on an I-CIMS.  
60 Similar lamps have been commonly used in atmospheric pressure photoionization-mass spectrometry (e.g. Kauppila et al., 2017). The vacuum ultraviolet (VUV) light is generated from two emission lines centered at ~~447116.486~~ (photon energy = 10.~~6641~~ eV) and ~~424123.582~~ nm (photon energy = 10.~~030~~ eV). CH<sub>3</sub>I has a large absorption cross section ( $7 \times 10^{-17}$  cm<sup>2</sup>

molecule<sup>-1</sup>) at these wavelengths and a relatively low ionization potential (IP =  $9.54 \pm 0.02$  eV) (Holmes and Lossing, 1991; Olney et al., 1998). Absorption of the VUV light by CH<sub>3</sub>I forms cations and relatively low energy photoelectrons which can then ~~be attached by~~attach to CH<sub>3</sub>I to form I<sup>-</sup>. Benzene (C<sub>6</sub>H<sub>6</sub>) can also serve as a VUV absorber to produce photoelectrons as it has a larger absorption cross section ( $4 \times 10^{-17}$  cm<sup>2</sup> molecule<sup>-1</sup>) and an even lower IP ( $9.24378 \pm 0.00007$  eV) (Nemeth et al., 1993; Capalbo et al., 2016). We explore the use of C<sub>6</sub>H<sub>6</sub> as a source of photoelectrons as we have found that delivering even modest quantities of gas phase CH<sub>3</sub>I to our ion source can be problematic as it has a tendency to polymerize to non-volatile species in compressed gas cylinders. Tests of C<sub>6</sub>H<sub>6</sub> as a photoelectron source in this work are performed as it may enhance ion production when used in combination with lower levels of CH<sub>3</sub>I. C<sub>6</sub>H<sub>6</sub> may also be used as an electron source for use with other electron attaching compounds with higher IPs, such as SF<sub>6</sub>, to form reagent ions such as SF<sub>6</sub><sup>-</sup>.

The performance of the VUV-IS was characterized by measuring the sensitivities on a quadrupole CIMS (Q-CIMS) to formic acid, chlorine (Cl<sub>2</sub>), and nitril chloride (ClNO<sub>2</sub>), under different flow conditions with varying levels of CH<sub>3</sub>I. Similar tests were also performed using a flow of both C<sub>6</sub>H<sub>6</sub> and CH<sub>3</sub>I through the ion source. Potential interferences due to the VUV light interacting with air or surfaces are investigated by comparing ambient mass spectra obtained with a VUV-IS and a standard 20 mCi <sup>210</sup>Po ion source (NRD Static Control, P-2031) on both a commercial high resolution time-of-flight CIMS (TOF-CIMS) and a Q-CIMS. We also test the potential of measuring PAN using this VUV-IS on a TD (thermal dissociation)-CIMS. The reliability of the VUV-IS is tested by performing field measurements for a six week time period at a remote location. The potential of extending the use of VUV-IS to SF<sub>6</sub><sup>-</sup> and airborne operation is also explored.

## **2. Materials and Methods**

### **2.1 Quadrupole I-CIMS and experimental configurations**

The Q-CIMS used here is very similar to the system that has measured a variety of species such as Cl<sub>2</sub>, BrO, and PAN, and has been detailed in previous publications (Slusher et al., 2004; Liao et al., 2011; Liao et al., 2014; Lee et al., 2019). Details specific to these experiments are described below. A diagram of the I-CIMS system and the experimental layout is shown in Figure 1. Varying levels of calibration standard were added to 4-10 standard liters per minute (slpm) of N<sub>2</sub> and delivered to the sampling inlet of the CIMS through perfluoroalkoxy (PFA) Teflon tubing, with dimensions of 1.27 cm outer diameter, and 0.95 cm inner diameter. Approximately 1.6 slpm of this flow was sampled into the CIMS flow tube and the rest was exhausted into the lab. The flow tube was humidified by adding 20 standard cubic centimeters per minute (sccm) of N<sub>2</sub> through a water bubbler kept in an ice bath. The flow tube was operated at a pressure of either 20 or 40 Torr by using either a 0.91 mm or 0.635 mm orifice between the flow tube and the collisional dissociation chamber (CDC). The scroll pump flow was controlled to maintain the flow tube at 20 or 40 Torr.

Mass spectra of ambient Atlanta air were obtained, in order to check for potential interferences due to the VUV-IS. For these experiments air was sampled from the roof of the Environmental Science and Technology building on the Georgia Tech campus. A PFA Teflon tube of 0.95 cm inner diameter and 8 m long was used as a sampling inlet. A total flow of ~7 slpm of ambient air was drawn through the inlet, of which 1.7 slpm was sampled into the CIMS flow tube and the rest was exhausted through a diaphragm pump. The flow tube was ~~operated~~controlled at 20 Torr.

## 2.2 Calibration sources

Permeation tubes (KIN-TEK Laboratories, Inc.) were used as the sources of Cl<sub>2</sub> and formic acid for tests on the Q-CIMS. The output of ~~both tubes~~formic acid tube was measured by ion chromatography (Metrohm Herisau, 761 Compact IC) as detailed by ~~Liao et al. (2014) and~~ Nah et al. (2018). The Cl<sub>2</sub> permeation tube emission rate was measured by conversion to I<sub>3</sub><sup>-</sup> in aqueous solution, and the resulting I<sub>3</sub><sup>-</sup> was quantified by optical absorption at 352 nm on a spectrophotometer (Finley and Saltzman, 2008). The permeation rates were measured to be 104.7 ± 7.8 ng min<sup>-1</sup> for formic acid and 14.8 ± 1.2 ng min<sup>-1</sup> for Cl<sub>2</sub>. A ClNO<sub>2</sub> standard-~~gas~~ was generated by passing a humidified flow of Cl<sub>2</sub> from the permeation tube in N<sub>2</sub> through a bed of sodium nitrite (NaNO<sub>2</sub>). The yield of ClNO<sub>2</sub> from Cl<sub>2</sub> was assumed to be 50% as we have consistently found in previous studies (Liu et al., 2017).

Sensitivity tests to formic acid and Cl<sub>2</sub> on a TOF-CIMS were performed by standard addition in laboratory air. The calibration species were obtained from a calibrated formic acid permeation device (47 ng min<sup>-1</sup>) and a 4 ppm Cl<sub>2</sub> in N<sub>2</sub> compressed gas cylinder. The Cl<sub>2</sub> cylinder was calibrated by cavity ring-down spectroscopy (CRDS) at 405 nm. The permeation rate of formic acid was measured by catalytic conversion to CO<sub>2</sub> followed by CO<sub>2</sub> detection as detailed by Veres et al. (2010).

## 2.3 VUV ion source (VUV-IS)

In a typical I<sup>-</sup>-CIMS system, a flow of CH<sub>3</sub>I in N<sub>2</sub> ~~is passed~~passes through a <sup>210</sup>Po radioactive ion source, to form the reagent ion I<sup>-</sup>. In this study, the radioactive source was removed and replaced with a VUV lamp assembly. The Kr lamp is powered by a 4 W DC power supply- (UltraVolt® AA Series High-Voltage Biasing Supplies). Two configurations (a and b as shown in Figure 1) of the VUV lamp assembly were tested. In both configurations a small Kr VUV lamp (Heraeus, Type No. PKS 106) (19.6 mm diameter × 53.5 mm length) was used to generate ions. This lamp is commonly used in small commercial VOC detectors that utilize photoionization as a detection method. The lifetime of this lamp is estimated to be 4000 hours (~5.5 months of continuous use) by the manufacturer. The VUV lamp was operated at ~280 Volts DC and typically drew ~0.7 mA. In general, the ion current reaching the mass spectrometer increased with increasing lamp voltage (see Figure S1). The VUV lamp was attached to a custom QF 40 centering ring with vacuum epoxy. The centering ring has a thru hole (11.4 mm diameter) with a counterbore (41.1 mm diameter) in the center. The lamp is sealed to the edge of the counterbore with vacuum epoxy. The thru hole allows light from the lamp to enter the ion source region of the CIMS. The QF 40 centering ring is mated on

the low pressure side to an inline tee with two QF 40 flanges on the ends and a 0.635 cm NPT fitting in the center. In lamp configuration (a), the inline tee is attached to a standard short QF 40 nipple (126 mm length) which serves as a photoionization region and provides a direct path for the VUV photons and generated ions into the flow tube. In configuration (b), a QF 40 90 degree elbow was attached between the QF 40 nipple and CIMS flow tube to prevent direct exposure of the flow tube to the VUV photons. The ambient pressure side of the QF 40 centering ring, on which the VUV lamp attached, is mated to a QF 40 × QF 16 × QF 40 reducing tee housing for protection of the VUV lamp. The QF 16 branch of the tee enables visual inspection of the lamp operation.

The sensitivity of the VUV-IS for measuring formic acid, Cl<sub>2</sub> and ClNO<sub>2</sub> was measured for varying CH<sub>3</sub>I concentrations and at two flow tube pressures (Table 1 and 2). The impact of adding C<sub>6</sub>H<sub>6</sub> was investigated by varying the concentration of C<sub>6</sub>H<sub>6</sub> at a lower level of CH<sub>3</sub>I. Compressed gas cylinders of ~700 ppmv of CH<sub>3</sub>I and ~0.1% of C<sub>6</sub>H<sub>6</sub> in N<sub>2</sub> were used as CH<sub>3</sub>I and C<sub>6</sub>H<sub>6</sub> sources. A variable flow of N<sub>2</sub> containing CH<sub>3</sub>I was delivered into the ion source to determine the optimal flow (Figure 2). The total ion source flow was regulated at 1 slpm for lamp configuration (a) and 1.2 slpm for lamp configuration (b) in all sensitivity and interference tests. Mixing ratios of CH<sub>3</sub>I and C<sub>6</sub>H<sub>6</sub> mentioned in the following sections are the mixing ratios in the total ion source flow (1 or 1.2 slpm).

## 2.4 TOF-CIMS

The VUV-IS was also characterized by operation on a commercial TOF-CIMS (Aerodyne Research Incorporated) (Lee et al., 2014); Veres et al., 2020). The ion molecule reactor (IMR) used here was constructed from a 150 mm long QF 40 adapter tee with a 9.5 mm fitting in the center, to allow mounting of the VUV-IS. The VUV lamp mounted to the QF 40 inline tee (section 2.1) was attached to a QF 40 × QF 16 conical adapter connected to a flange with a 9.5 mm stainless steel tube. This allowed the VUV-IS assembly to be mated directly to the IMR using standard vacuum components. The IMR was maintained at a pressure of 30 Torr and operated at a total flow of 2.2 slpm. A 1 slpm N<sub>2</sub> flow with 30-400 ppmv CH<sub>3</sub>I passed through the VUV-IS into the IMR and mixed with 1.2 slpm of ambient air. Water was dynamically added to the IMR to maintain a constant ratio of I<sup>-</sup> to I(H<sub>2</sub>O). This provided real-time compensation for changes in ambient humidity to minimize fluctuations in sensitivity. Mass spectra were obtained with both a VUV-IS and a standard radioactive ion source, sampling ambient air in Boulder Colorado.

## 3 Results

### 2.5 TD-CIMS

The sensitivity of TD-CIMS with a VUV-IS (Slusher et al., 2004) was also tested for PAN. The configuration of the TD-CIMS system used in this work is almost identical to that described in Lee et al. (2019) with the radioactive source replaced with the VUV-IS in configuration (b). A known amount of PAN was generated using a photolytic source similar to that described by

Warneck and Zerbach (1992). A calibration standard of 1 ppbv of PAN was produced by adding the output of the photolytic source to PAN free ambient air. PAN free air was generated by passing ambient air through a QF 40 nipple filled with stainless steel wool heated to 150 °C (Flocke et al., 2005).

## 2.6 SF<sub>6</sub><sup>-</sup>-CIMS

The instrument used to test the VUV-IS with SF<sub>6</sub><sup>-</sup> as a reagent ion is nearly identical to that used previously to measure BrO on the NCAR GV research aircraft (Chen et al., 2016). The operating parameters of the instrument are very similar to those used previously to simultaneously detect sulfur dioxide, formic, and acetic acid (Nah et al., 2018). However, in this application the radioactive ion source was replaced with a VUV-IS in configuration (b). The system was periodically calibrated in flight by adding a known amount of isotopically labeled <sup>34</sup>SO<sub>2</sub> into the sampled air flow.

~~3. Results~~ ~~The sensitivity of the VUV-IS on the Q-CIMS can reach 100s of Hz pptv<sup>-1</sup> (Table 1 and 2) similar to the best sensitivity obtained with radioactive sources (e.g. Lee et al., 2019).~~ Configuration (a) of the VUV-IS gives the highest signal levels (Figure 3) especially at lower flow rates through the ion source. However, configuration (a) also leads to significantly higher levels of interfering masses than configuration (b) due to photoelectrons being generated on the illuminated surface of the flow tube (Figure 4). Configuration (b) yields lower signals but significantly reduces background ion generation relative to configuration (a). The VUV-IS requires significantly higher levels of CH<sub>3</sub>I than those used in radioactive sources (typically ~1 ppmv, Slusher et al., 2004) (Figure 3 and 5), because the CH<sub>3</sub>I must also serve as a source of photoelectrons. C<sub>6</sub>H<sub>6</sub> can be used as a VUV absorber to generate photoelectrons (Figure 3 and 5) without generating excessive interferences (Figure 4). Tests on the TOF-CIMS demonstrated that the VUV-IS and a standard radioactive ion source produced the same reagent ion (F<sup>-</sup>) abundance. In addition, both sources generated similar mass spectra of ambient air, demonstrating that the VUV-IS source did not produce significant interferences to the detection of most trace gases (Figure 6).

### 3.1 Q-CIMS Sensitivities using CH<sub>3</sub>I

The sensitivities and LODs for formic acid, Cl<sub>2</sub> and ClNO<sub>2</sub> under different experimental conditions using lamp configuration (b) are compiled in Table 1. With the flow tube at 20 Torr, sensitivities to formic acid, Cl<sub>2</sub> and ClNO<sub>2</sub> reached up to 147, 161 and 154 Hz pptv<sup>-1</sup>, respectively, using up to 86.5 ppmv of CH<sub>3</sub>I in the ion source flow. At 40 Torr, similar sensitivities (128, 149 and 148 Hz pptv<sup>-1</sup> for formic acid, Cl<sub>2</sub> and ClNO<sub>2</sub>, respectively) were achieved with less CH<sub>3</sub>I (19.0 ppmv). Figure 53 shows the dependence of the CIMS sensitivities on the CH<sub>3</sub>I level at 20 Torr (upper left) and 40 Torr (lower left) with no other absorber added. In general, CIMS sensitivities increase with the CH<sub>3</sub>I mixing ratio. However, the response is less than linear and appears to saturate at higher levels of absorber. With the maximum concentration of CH<sub>3</sub>I (86.5 ppmv, 5.70×10<sup>13</sup> molecule cm<sup>-3</sup>) used in this experiment, ~8% of photons emitted from the VUV lamp were absorbed (see SI for sample calculation). This indicates that other factors such as ion recombination and wall loss could be limiting limit the ion abundance. The sensitivities and LODs under similar experimental conditions using lamp configuration (a) are show in Table 2 and Figure 34. The sensitivities to formic acid, Cl<sub>2</sub>, and ClNO<sub>2</sub> approached ~700 Hz pptv<sup>-1</sup>, with limits of detection of less than 1 pptv for a one minute integration period. Limits of detection are defined at a signal-to-noise ratio of 3 where the noise is the variance of the background measurements. In general, the sensitivities using lamp configuration (a) were about a factor of four

larger than in configuration (b). Note that all the Q-CIMS sensitivities reported in this work are not normalized to the reagent ion signal, since the reagent ion signal is not known accurately. We estimate the reagent ion signals are ~100 MHz at the highest sensitivities, but the Q-CIMS detector counts ions linearly only up to about 0.5 MHz.

### 195 3.2 Q-CIMS Sensitivities using CH<sub>3</sub>I and C<sub>6</sub>H<sub>6</sub>

In order to test the effectiveness of the addition of another absorber to generate photoelectrons, mixtures of CH<sub>3</sub>I and C<sub>6</sub>H<sub>6</sub> were added to the ion source. Lower mixing ratios (8.8 ppmv at 20 Torr, 1.8 ppmv at 40 Torr) of CH<sub>3</sub>I were used in combination with varying amounts of C<sub>6</sub>H<sub>6</sub> to assess the impact of the addition of C<sub>6</sub>H<sub>6</sub> to the generated ion current using lamp configuration (b). The sensitivity dependence on C<sub>6</sub>H<sub>6</sub> mixing ratio is shown in Figure 53. At 20 Torr, up to 229.2 ppmv C<sub>6</sub>H<sub>6</sub> was added to 8.8 ppmv CH<sub>3</sub>I to achieve the equivalent sensitivity (158, 157, and 152 Hz pptv<sup>-1</sup> for formic acid, Cl<sub>2</sub> and ClNO<sub>2</sub>, respectively) using 86.5 ppmv CH<sub>3</sub>I alone. At 40 Torr, up to 58.9 ppmv C<sub>6</sub>H<sub>6</sub> was added to 1.8 ppmv of CH<sub>3</sub>I to reach the maximum level of sensitivities (157, 166, and 138 Hz pptv<sup>-1</sup> for formic acid, Cl<sub>2</sub> and ClNO<sub>2</sub>, respectively) when using 19.0 ppmv of CH<sub>3</sub>I. Similar trends for the addition of C<sub>6</sub>H<sub>6</sub> using lamp configuration (a) was observed and are shown in Table 2 and Figure 34. At both 20 and 40 Torr sensitivities of more than 600 Hz pptv<sup>-1</sup> were obtained for all species in configuration (a). These results demonstrate that addition of an absorber (e.g. benzene C<sub>6</sub>H<sub>6</sub>) enables high sensitivity with the VUV-IS while adding typical levels (a few ppmv) of an electron attaching compound.

### 3.3 Q-CIMS Interference Tests

Representative mass spectra (m/z = 20 - 220 amu) taken with a 20 mCi <sup>210</sup>Po standard radioactive source and the VUV-IS with configuration (a) on an I-CIMS sampling ambient air are shown in Figure 45. Note that the I<sup>-</sup> signal is saturated in all mass spectra due to the very high signal levels. Clearly, the VUV-IS in configuration (a) generates many additional ions compared to a radioactive source. Large signals (> 100,000 Hz) are observed at O<sub>2</sub><sup>-</sup> (m/z = 32 amu), NO<sub>3</sub><sup>-</sup> (m/z = 62 amu), and CO<sub>3</sub><sup>-</sup> (m/z = 60 amu). This indicates that photoelectrons generated on the illuminated surface of the flow tube in the presence of the sampled air leads to formation of O<sub>2</sub><sup>-</sup> by electron attachment to O<sub>2</sub>. This also leads to the formation of CO<sub>3</sub><sup>-</sup> and NO<sub>3</sub><sup>-</sup> by subsequent reactions with CO<sub>2</sub>, O<sub>3</sub>, and NO<sub>2</sub> (Mohler and Arnold, 1991). Consequently, the generation of O<sub>2</sub><sup>-</sup> initiates significant secondary chemistry that may lead to interfering signals at a large number of masses.

Using the VUV-IS in configuration (b) prevents direct illumination of the flow tube by the VUV lamp and produces similar spectra to those obtained with a radioactive source (Figure 45). The O<sub>2</sub><sup>-</sup> signal levels are lower by more than three orders of magnitude compared to configuration (a) where the flow tube is directly illuminated.

Finally, Figure 45 also has a mass spectrum using the VUV-IS in configuration (b) with the addition of 110 ppmv of C<sub>6</sub>H<sub>6</sub> and 8.8 ppmv of CH<sub>3</sub>I in the ion source flow. The addition of the C<sub>6</sub>H<sub>6</sub> does not produce significant amounts of additional new ions

and the mass spectrum is very similar to that obtained without C<sub>6</sub>H<sub>6</sub>. This indicates that using C<sub>6</sub>H<sub>6</sub> (or other low IP compounds such as toluene or propene) as a light absorber to generate photoelectrons has the potential to extend the use of the VUV-IS to other electron attaching compounds (e.g. SF<sub>6</sub>, HNO<sub>3</sub>, etc.) that have small absorption cross sections in the VUV or have ionization potentials higher than 10.6 eV.

### 3.4 Q-CIMS Field Tests

Ground-based measurements of CINO<sub>2</sub>, dinitrogen pentoxide (N<sub>2</sub>O<sub>5</sub>) and formic acid using the I-CIMS with the VUV-IS were conducted at a rural site in Dongying, China, during the Ozone Photochemistry and Export from China Experiment (OPECE) campaign from March 20 to April 24, 2018. Continuous formic acid-The I-CIMS was deployed in a shelter, with neither heating nor air conditioning, in a remote location in a bird sanctuary in the Yellow River Delta. The site experienced intermittent power interruptions and large ambient temperature variations, from -2.5 to 29.1 °C, with the temperature inside the shelter ranging from ~10 to 40 °C.

The primary goal for the I-CIMS during the OPECE campaign was to measure halogen containing compounds. However, we found the presence of halogens to be intermittent. Figure 6 shows representative observations of CINO<sub>2</sub> and N<sub>2</sub>O<sub>5</sub> for this site when halogens were observed. This figure is consistent with the expected behavior of CINO<sub>2</sub> and N<sub>2</sub>O<sub>5</sub>, both accumulate during night time, and both decrease after sunrise due to photolysis of CINO<sub>2</sub> and thermal decomposition of N<sub>2</sub>O<sub>5</sub> followed by photolysis of NO<sub>3</sub>. CINO<sub>2</sub> is a product of reaction between N<sub>2</sub>O<sub>5</sub> and chloride containing aerosol (R1, Finlayson-Pitts et al., 1989), and CINO<sub>2</sub> and N<sub>2</sub>O<sub>5</sub> are well correlated (R<sup>2</sup> = 0.94, Figure 6(2)) during the night (6 pm, April 12 to 6 am, April 13). These measurements of CINO<sub>2</sub> and N<sub>2</sub>O<sub>5</sub> indicate the performance of the I-CIMS with the VUV-IS is sufficient to capture atmospheric levels and variability.

Formic acid which is routinely measured by I-CIMS and ubiquitous in the atmosphere as both an emission and a secondary chemical product was also monitored during the campaign. These observations demonstrate reliable field operation of the lamp for long periods that I-CIMS with a VUV-IS could be operated continuously for an extended period (Figure 7). A clogged mass flow controller on the inlet and a scroll pump failure caused brief measurement interruptions on March 27 and in early April. We could not obtain gas mixtures of CH<sub>3</sub>I at this field location, so we used a liquid reservoir as CH<sub>3</sub>I source. This led to using CH<sub>3</sub>I levels of ~~400s~~ hundreds of ppmv which may have accelerated degradation of the scroll pump tip seals. We also encountered some temperature control issues and power interruptions during the mission. However, no direct problems were encountered with the VUV-IS and. Online calibration of formic acid was performed every 30 minutes during the mission. The CIMS sensitivity to formic acid was measured to be 185.2 ± 48.3 Hz pptv<sup>-1</sup> during the first day, and 180.5 ± 24.3 Hz pptv<sup>-1</sup> a month later, so we did not notice any drop in sensitivity that could be attributed to a decrease in light intensity from the lamp. In addition, we have used in this work has been operational, with no the same VUV-IS since the OPECE field mission (Spring

2018) through early 2020 for both lab studies and field measurements, and have not found obvious degradation of signal, for over 18 months. –sensitivity degradations.

### 3.5 TOF-CIMS Tests

260 The VUV-IS was found to give very similar signal levels to those obtained with a standard radioactive ion source (with an activity of ~16 mCi of  $^{210}\text{Po}$ ) on a TOF-CIMS. Both sources gave total reagent ion signals of ~10 MHz and similar sensitivity to both formic acid and  $\text{Cl}_2$  of about 20-25 Hz/ppt. The  $\text{I}^-$  signal for both sources was ~6 MHz and the  $\text{I}^-(\text{H}_2\text{O})$  signal was ~3 MHz. In addition, as illustrated in Figure 68, both sources gave very similar mass spectra for ambient air. The largest difference between the mass spectra were that the VUV-IS gave higher levels of  $\text{I}_3^-$  while the radioactive source gave higher levels of peaks corresponding to nitric acid (i.e.  $\text{I}^-(\text{HNO}_3)$  and  $\text{NO}_3^-$ ). Sensitivities as a function of  $\text{CH}_3\text{I}$  mixing ratio in the flow tube were also tested (Figure S2). Sensitivities to formic acid and  $\text{Cl}_2$  increase with the  $\text{CH}_3\text{I}$  mixing ratio up to ~100 ppmv. The sensitivities normalized to the reagent ion  $\text{I}^-(\text{H}_2\text{O})$  do not change with  $\text{CH}_3\text{I}$  mixing ratio and are the same obtained with the radioactive source. These results demonstrate that a VUV-IS can be used on a TOF-CIMS to obtain the same sensitivity, selectivity, and ion distribution as with a radioactive ion source.

## 270 **4 Discussion**

### Clearly, the 3.6 PAN Measurement Tests

Preliminary tests using the Q-CIMS as a TD-CIMS demonstrated the potential of the VUV-IS for use in the measurement of PAN. Mass spectra of ambient air with and without PAN are shown in Figure S3. The sensitivity towards PAN was observed to be 49.4 Hz/pptv with an LOD (Signal to noise ratio = 3:1) of 0.64 pptv for a 1 minute integration. No significant interferences were observed during the ambient air tests.

275

### 3.7 SF<sub>6</sub>-Q-CIMS Tests

Preliminary aircraft-based measurements of sulphur dioxide, formic and acetic acid using the SF<sub>6</sub>-CIMS with the VUV-IS were conducted during an Asian Summer Monsoon Chemical and Climate Impact Project (ACCLIP) test flight based out of Broomfield, Colorado on January 30, 2020. Time series of formic and acetic acid signals are shown in Figure S4(1). The signals of formic and acetic acid are correlated ( $R^2 = 0.63$ , Figure S4(2)) as observed in previous studies (Souza and Carvalho, 2001; Paulot et al., 2011; Nah et al., 2018). We did not perform online calibrations for formic or acetic acid. Sensitivities to formic and acetic acids during this test flight are estimated to be 5-20 Hz/pptv based on online calibrations of  $^{34}\text{SO}_2$  and measurements of the ratio of their sensitivities (Nah et al., 2018).

280

#### 4. Discussion

285 The VUV-IS can generate  $I^-$  ions and mass spectra that are very similar to a radioactive ion source on both a TOF-CIMS and a Q-CIMS. For this reason, we think that the VUV-IS can replace radioactive ion sources in most  $I^-$ -CIMS applications without any loss of measurement performance. Perhaps, the largest benefit of the VUV-IS is that it will expand the use of  $I^-$ -CIMS to locations or situations where radioactivity is not allowed. The VUV-IS is also likely to be useful for laboratory flow tube or chamber studies that use CIMS as a detector (D'Ambro et al., 2017; Huang et al., 2017; Faxon et al., 2018). We have not found  
290 any interferences or issues that would limit application of a VUV-IS, though its application to measurement of individual species must be confirmed by further testing.

Using the VUV-IS requires attention to the possibility of interferences caused by the generation of photoelectrons from surfaces that can be attached by oxygen or other compounds in the sampled gas matrix. We were able to minimize this effect by using  
295 a flow geometry that shielded the flow tube from the VUV photons albeit at the expense of more than a factor of four in signal on the Q-CIMS. Similarly, the implementation of the VUV-IS on the TOF-CIMS successfully limited  $O_2^-$  production by passing the ion source flow through a small diameter tube that discriminated against light reaching the IMR. This issue might also be addressed by further improvements in geometry, the use of optical focusing elements, or higher levels of an absorber molecule.

300

The VUV-IS source requires an absorbing species to serve as a source of photoelectrons. Extending the use of the VUV-IS to other reagent ions such as  $SF_6^-$  (Nah et al., 2018),  $Br^-$  (Sanchez et al., 2016),  $NO_3^-$  (Eisele and Tanner, 1993),  $CF_3O^-$  (Crouse et al., 2006), and  $CH_3CO_2^-$  (Veres et al., 2008) ~~will most likely require~~requires the addition of an absorber such as  $C_6H_6$  or  
305  $C_7H_8$ . Although the use of  $CH_3I$  to produce  $I^-$  with the VUV-IS does not require an additional absorber, this application requires relatively high levels of  $CH_3I$  to obtain maximum sensitivities. Since  $CH_3I$  is a hazardous gas, higher levels of  $CH_3I$  could be problematic for some situations such as deployment in a highly regulated environment such as an aircraft. Higher levels of  $CH_3I$  may also necessitate protection of scroll pumps with scrubbers and traps. For these reasons, it may be preferable to use a low activity (Lee et al., 2019) or standard radioactive ion source for some applications.

310 One potential advantage of the VUV-IS is demonstrated by the lower background signals at masses corresponding to nitric acid ( $HNO_3$ ). This is probably due to lower rates of nitrogen radical generation in the VUV-IS as the generated photons are much lower in energy ( $\sim 10$  eV) relative to the alpha particles ( $\sim 5.4$  MeV) from a  $^{210}Po$  radioactive source. Additionally, the VUV-IS does not produce ions when power is removed but radioactive decay is continuous. Consequently, interfering species can be continuously generated in a radioactive source, leading to build up of condensable species such as nitric acid. For these  
315 reasons, the VUV-IS may generate significantly lower levels of interferences than a radioactive source.

## 5. Summary and Conclusions

The sensitivity of the VUV-IS on the Q-CIMS can reach 100s of Hz pptv<sup>-1</sup> (Table 1 and 2) similar to the best sensitivity obtained with radioactive sources (e.g. Lee et al., 2019). Care must be taken to avoid illuminating surfaces in the CIMS exposed to air. The VUV-IS requires significantly higher levels of CH<sub>3</sub>I than used in radioactive sources (typically ~1 ppmv, Slusher et al., 2004) (Figure 3 and 4), because the CH<sub>3</sub>I must also serve as a source of photoelectrons. C<sub>6</sub>H<sub>6</sub> and other species can be used as a VUV absorber to generate photoelectrons (Figure 3 and 4) without generating excessive interferences (Figure 5). Tests on a TOF-CIMS demonstrated that the VUV-IS and a standard radioactive ion source produced the same reagent ion (I<sup>-</sup>) abundance. In addition, both sources generated similar mass spectra of ambient air, demonstrating that the VUV-IS source did not produce significant interferences to the detection of most trace gases (Figure 8). Preliminary tests also indicate the VUV-IS is compatible with TD-CIMS and SF<sub>6</sub><sup>-</sup>-CIMS methods as well as airborne operation.

The VUV-IS described in this work ~~can provide~~provides sensitivities and limits of detections that are at least comparable to those obtained with a radioactive ion source for both Q-CIMS and TOF-CIMS using I<sup>-</sup> as a reagent ion. The VUV-IS is ~~also~~ reliable and can be safely deployed in remote field missions. These results demonstrate that the VUV-IS can eliminate the need for radioactivity with an I-CIMS for most applications. The use of low IP absorbers, such as ~~benzene~~C<sub>6</sub>H<sub>6</sub>, to generate photoelectrons in conjunction with high IP electron attaching compounds ~~should also allow~~allows the generation of other reagent ions such as SF<sub>6</sub><sup>-</sup>, CF<sub>3</sub>O<sup>-</sup>, and NO<sub>3</sub><sup>-</sup>. In summary, the VUV-IS has the potential to eliminate most of the use of radioactivity with CIMS instruments.

### *Data Availability*

335 All of the data used in this manuscript is available upon request of the corresponding author.

### *Author Contributions*

Yi Ji performed all of the Q-CIMS experiments and wrote the manuscript with assistance from Greg Huey. David Tanner assisted with all the experiments. Xinming Wang organized the OPECE campaign and provided the  $j_{NO_2}$  data. All of the authors were involved in data interpretation and commented on the manuscript. The TOF-CIMS experiments were performed  
340 by Patrick Veres, Andy Neuman, and Greg Huey.

### *Competing Interests*

The authors declare that they have no conflicts of interest.

## Acknowledgements

**Figure 1.** Diagram of the I-Q-CIMS system with a VUV-IS in two different configurations. Configuration (a) provides the most direct route for the generated ions but also directly illuminates the flow tube. Configuration (b) shields the flow tube from the VUV photons by inserting a QF 40 elbow between the photoionization region and the flow tube.

525 **Figure 2:** Q-CIMS sensitivity to Cl<sub>2</sub><sup>-</sup> (m/z = 197 amu) as a function of total ion source flow using the VUV-IS with lamp configuration (a) and (b).

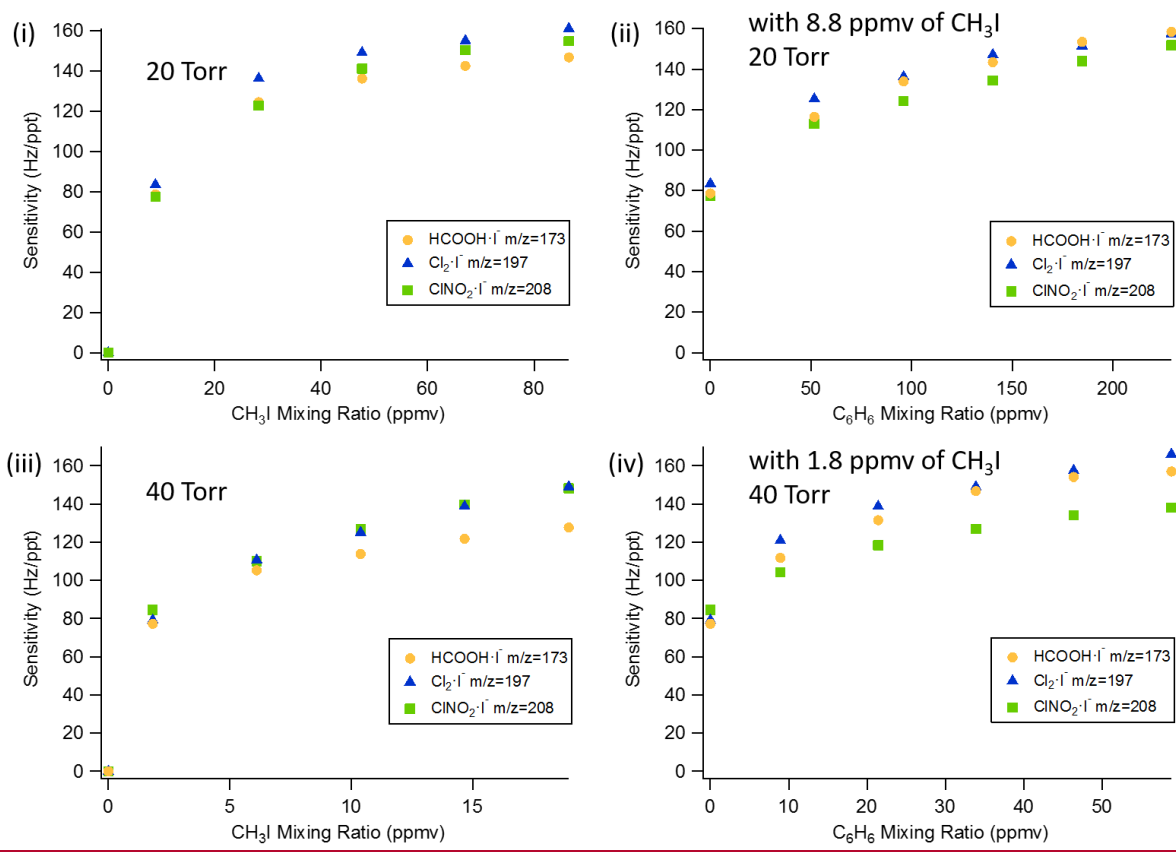

Figure 3: Q-CIMS using VUV-IS configuration (a): Upper left panel (b): (i) sensitivity as a function of CH<sub>3</sub>I at 20 Torr. Upper right panel (ii) sensitivity as a function of C<sub>6</sub>H<sub>6</sub> at 20 Torr. Lower left panel (iii) sensitivity as a function of CH<sub>3</sub>I at 40 Torr. Lower right panel (iv) sensitivity as a function of C<sub>6</sub>H<sub>6</sub> at 40 Torr, with 1.8 ppmv of CH<sub>3</sub>I.

530

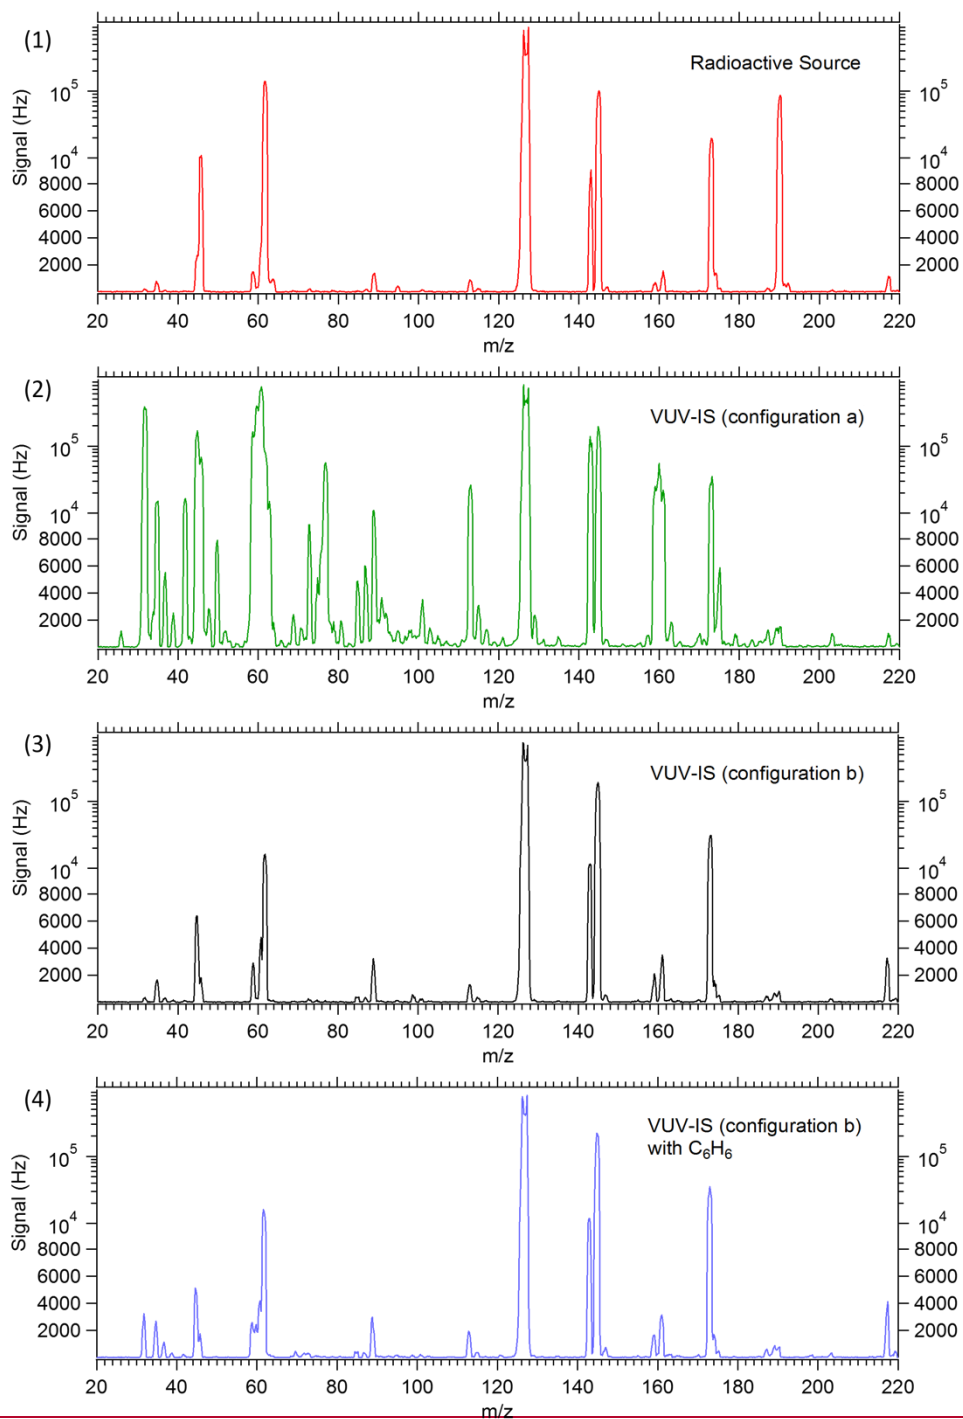

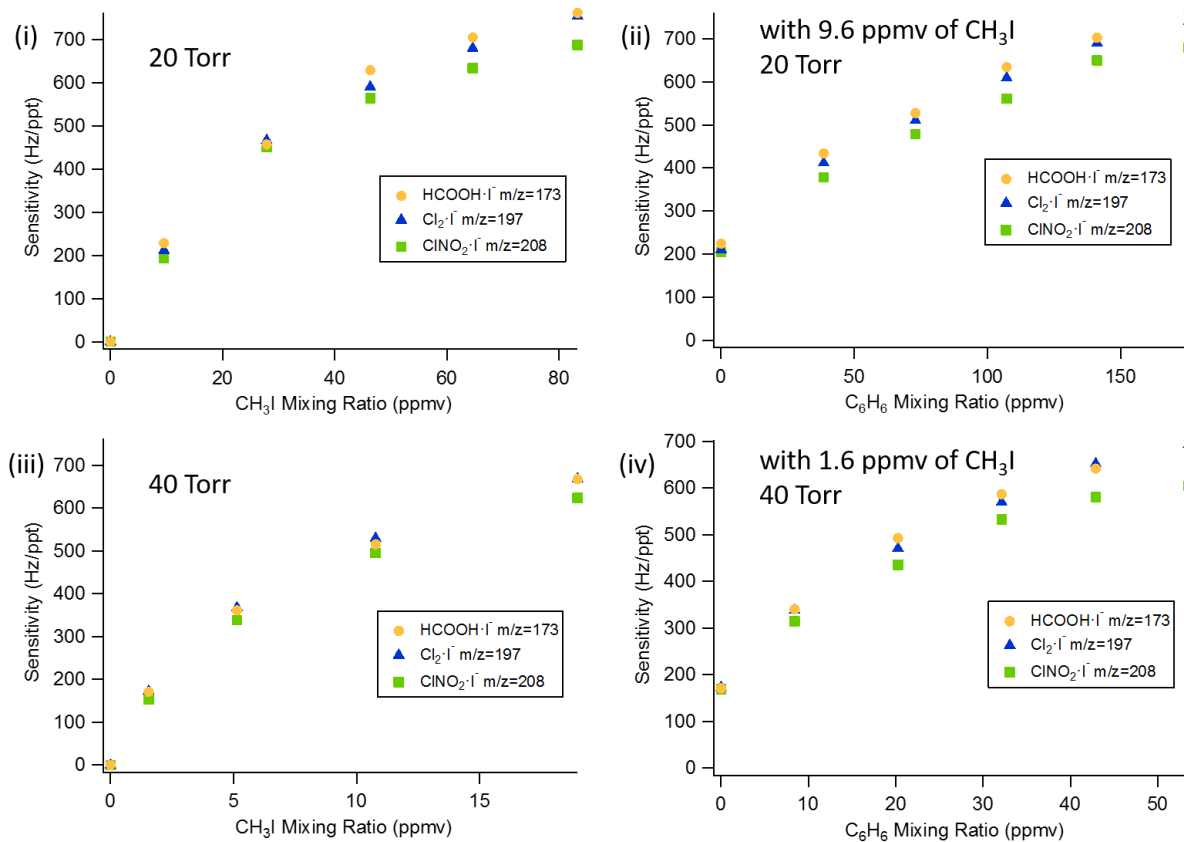

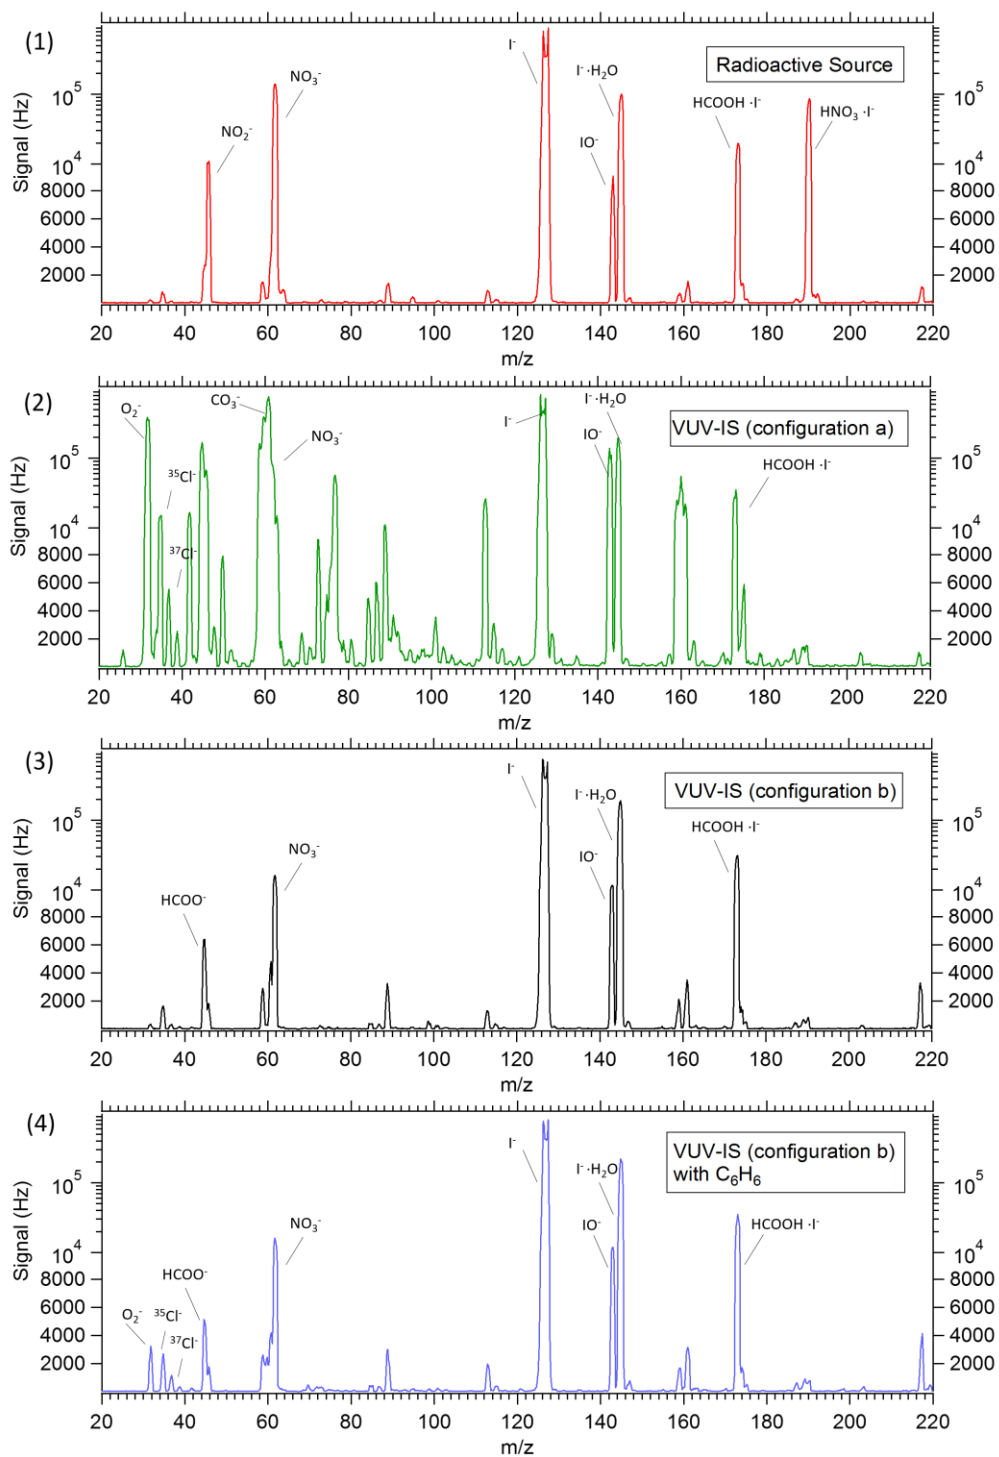

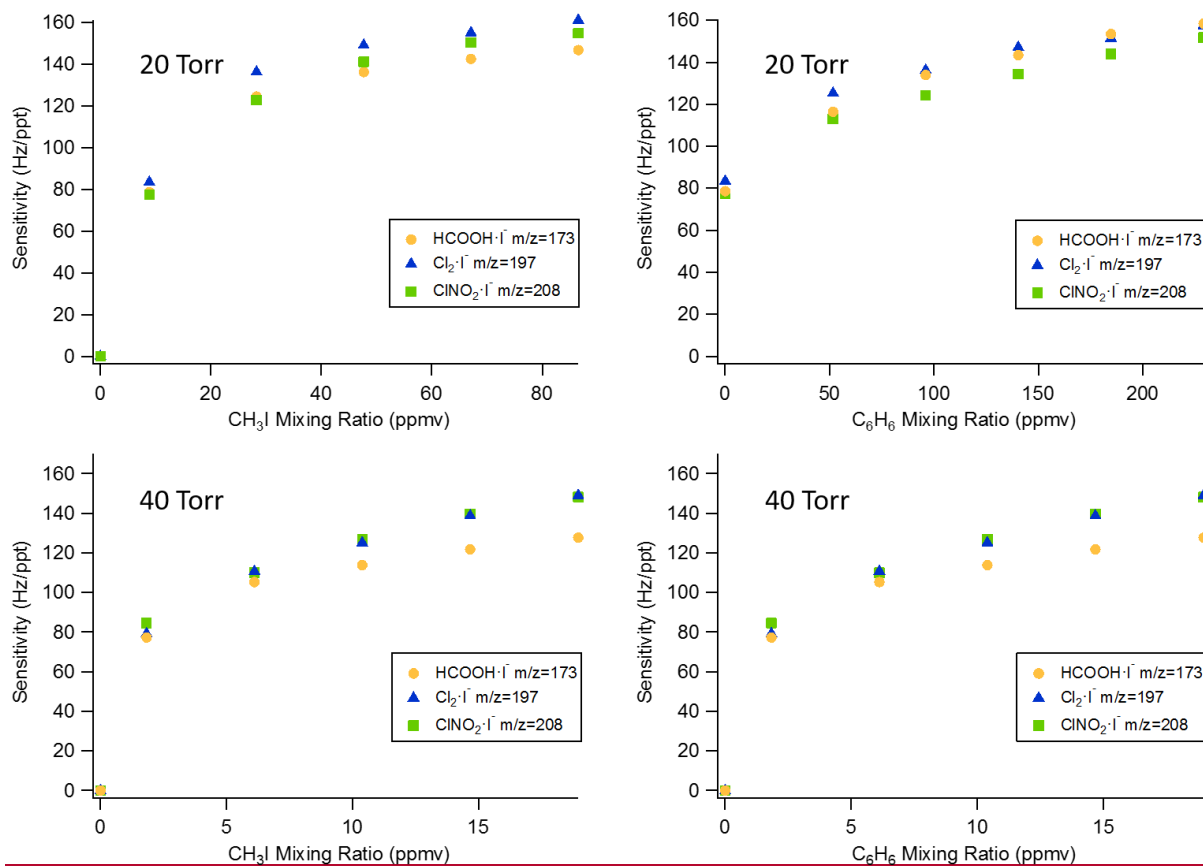

Figure 4:

535 **Figure 4. O-CIMS using VUV-IS configuration (a): (i) sensitivity as a function of CH<sub>3</sub>I at 20 Torr. (ii) sensitivity as a function of C<sub>6</sub>H<sub>6</sub> at 20 Torr with 9.6 ppmv of CH<sub>3</sub>I. (iii) sensitivity as a function of CH<sub>3</sub>I at 40 Torr. (iv) sensitivity as a function of C<sub>6</sub>H<sub>6</sub> at 40 Torr with 1.6 ppmv of CH<sub>3</sub>I.**

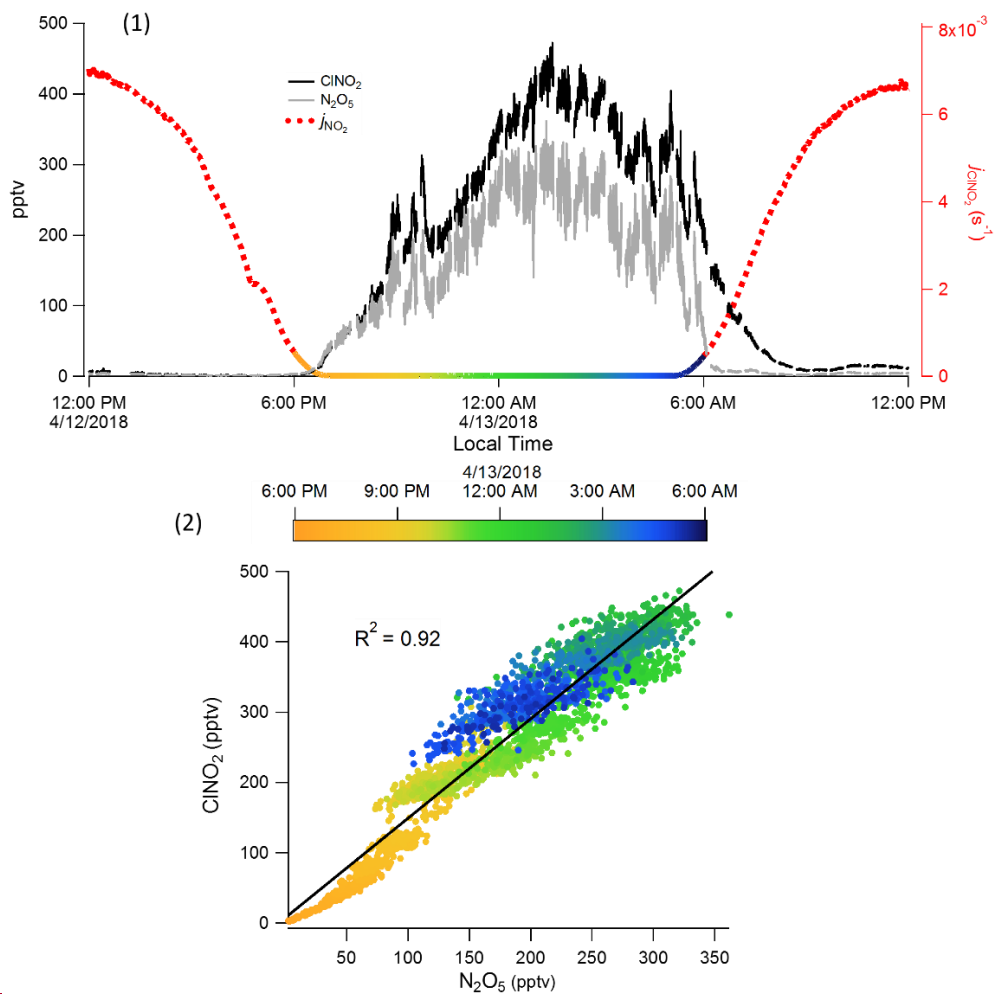

**Figure 5.** Mass spectra of ambient air from a Q-CIMS with (1) a standard radioactive ion source, (2) VUV-IS in configuration (a), (3) VUV-IS in configuration (b), and (4) VUV-IS in configuration (b) with  $\sim 100$  ppmv of  $\text{C}_6\text{H}_6$  and  $\sim 10$  ppmv of  $\text{CH}_3\text{I}$ . Note that the  $\text{I}^-$  signal is saturated in all mass spectra.

**Figure 5: Q-CIMS using VUV-IS configuration (b): Upper left panel—sensitivity as a function of CH<sub>3</sub>I at 20 Torr. Upper right panel—sensitivity as a function of C<sub>6</sub>H<sub>6</sub> at 20 Torr. Lower left panel—sensitivity as a function of CH<sub>3</sub>I at 40 Torr. Lower right panel—sensitivity as a function of C<sub>6</sub>H<sub>6</sub> at 40 Torr.**

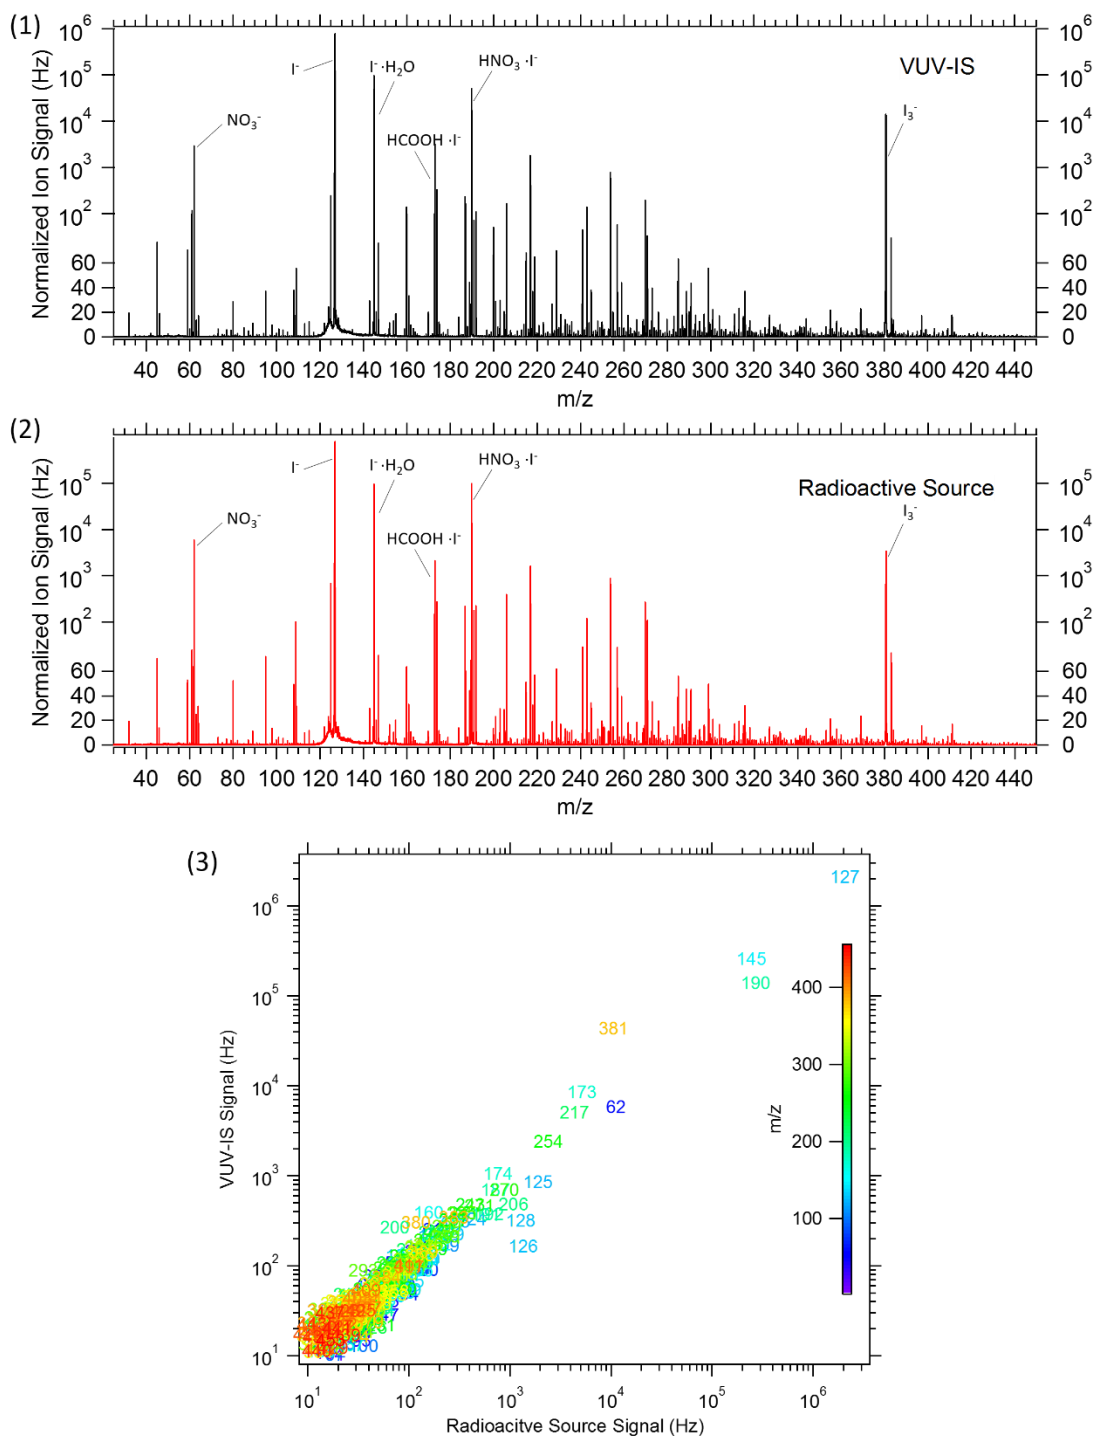

**Figure 6.**

**Figure 6. Measurements of  $\text{ClNO}_2$  and  $\text{N}_2\text{O}_5$  using I-CIMS with VUV-IS between 12 pm of April 12 and 12 pm of April 13, 2018 during OPECE campaign. (1) time series along with  $j_{\text{NO}_2}$  (to delineate night and day) and (2) a correlation plot of  $\text{ClNO}_2$  concentration versus  $\text{N}_2\text{O}_5$  concentration during the night time (6 pm, April 12 to 6 am, April 13).**

550

**Figure 7. Time series of ambient formic acid concentrations measured by I-CIMS with VUV-IS from March 20 to April 22, 2018 during OPECE campaign.**

555 **Figure 8.** Mass spectra of ambient air in Boulder, CO from a TOF-CIMS with (1) a VUV-IS (2) a radioactive source. The bottom panel (3) is a correlation plot of the individual mass signals with the VUV-IS versus those obtained with a radioactive source, with each ion labeled by its nominal mass.
