13 **Abstract**

14 Obtaining precise continuous measurements of water vapor isotopic composition in dry places (polar or  
15 high-altitude regions) is an important challenge. The current limitation is the strong influence of humidity  
16 on the measured water isotopic composition by laser spectroscopy instruments for low humidity levels  
17 (below 3000 ppmv). This problem is addressed by determining the relationships between humidity and  
18 measured  $\delta^{18}\text{O}$  and  $\delta\text{D}$  of known water standards. We present here the development of a robust field  
19 instrument able to generate water vapor, down to 70 ppmv, at very stable humidity levels (average 1σ  
20 lower than 10 ppmv). This instrument, operated by a Raspberry interface, can be coupled to a commercial  
21 laser spectroscopy instrument: it turned to be very stable in an autonomous mode during more than one  
22 year at the East Antarctic Concordia station.

23

24

25 **1. Introduction**

26 The recent development of laser spectroscopy instruments now enables the continuous measurement of  
27 the isotopic composition of water vapor at many observation stations all around the world (Bailey et al.,  
28 2015; Bastrikov et al., 2014; Schmidt et al., 2010; Sodemann et al., 2017; Tremoy et al., 2011). In particular,  
29 the isotopic composition of the water vapor has proven to be a very useful tool to document moist synoptic  
30 events in many locations (Bonne et al., 2014; Guilpart et al., 2017). In polar regions, the water vapor  
31 isotopic signal is not only useful to detect the origin of moist air (Bréant et al., 2019; Kopec et al., 2014)  
32 but also to improve the interpretation of the isotopic composition of water in surface snow and ice core  
33 archives (Steen-Larsen et al., 2014). Indeed, exchanges are occurring after deposition between the surface  
34 snow and the water vapor leading to modifications of the isotopic composition of the former and hence  
35 of the archived ice (Casado et al., 2016, 2018; Ritter et al., 2016).

36 Obtaining continuous measurements of the water vapor isotopic composition at Concordia station in  
37 central Antarctica is a key scientific challenge since the deep ice core drilled there, EPICA Dome C, provides  
38 the oldest continuous water isotopic record to date (Jouzel et al., 2007). It is thus a key reference for the  
39 study of past climate, and a correct interpretation of the isotopic record relies on the quantification of the  
40 transfer function between climate parameters and water isotopic composition in ice, itself influenced by  
41 exchanges with water vapor in the upper layers of the firn (Casado et al., 2018). Such knowledge is also of  
42 uttermost importance for the interpretation of water isotope records from the starting deep drilling  
43 project “Beyond EPICA-Oldest Ice” (<https://www.beyondepica.eu>), whose aim is to drill a 1.5-million-year  
44 old ice core on the Little Dome C site located 40 km away from Concordia station, hence with similar low  
45 temperature and humidity conditions.

46 One of the main limitations of the current commercial instruments when deployed in polar regions is their  
47 relatively poor performance at low water vapor concentration. Generally, the precision of the measured  
48 isotopic ratios  $\delta^{18}\text{O}$  and  $\delta\text{D}$  rapidly worsens when the water mixing ratio decreases to humidity levels  
49 below 3,000-5,000 ppmv (part-per-million per volume) (Bonne et al., 2014; Weng et al., 2020). However,  
50 in remote continental areas in Greenland and Antarctica, temperatures in winter can drop to very low  
51 values, leading to humidity levels down to 10 ppmv (Genthon et al., 2017). Arguably one of the most  
52 extreme experiments for continuous measurement of the water vapor isotopic composition was probably  
53 the deployment of a commercial Picarro L2130-i instrument at the East Antarctic French-Italian station of  
54 Concordia where the mean annual temperature is around  $-54^{\circ}\text{C}$  and the humidity barely exceeds 1000  
55 ppmv during the warmest summer days (Casado et al., 2016). For such applications, there are two major  
56 impacts of low humidity on the raw isotopic signal: first, we generally observe an apparent increase in the  
57  $\delta^{18}\text{O}$  and  $\delta\text{D}$  with decreasing humidity level and second, the standard deviation associated with the  
58 continuous measurements of  $\delta^{18}\text{O}$  and  $\delta\text{D}$  of the water vapor increases. It can thus lead to overall  
59 uncertainties of several ‰ for  $\delta^{18}\text{O}$  and tens of ‰ for  $\delta\text{D}$ . It is thus of uttermost importance to have a  
60 correct determination of the humidity dependency of the water vapor isotopic ratios.

61 Commercial instruments from Picarro Inc. are usually associated with a Picarro Standard Delivery Module  
62 (SDM) dedicated to generate humidity at stable levels between 5,000 and 30,000 ppmv. Using such a set-  
63 up for humidity levels below 5,000 ppmv leads to large uncertainties in the determination of the humidity  
64 influence on the water vapor isotopic composition (e.g. Guilpart et al., 2017). These uncertainties are due  
65 both to the instability of the water vapor generation using the SDM (in terms of water concentration –  
66 humidity– and/or isotopic composition) and due to the analytical noise in the spectroscopy  
67 measurements when the absorption signals are weak. An alternative commercial device is the LGR (Los  
68 Gatos Research) calibration system (water vapor isotope standard source, WVISS), which uses a nebulizer  
69 to instantaneously evaporate micro-droplets of liquid water from a standards reservoir into a large (1 L)

70 vaporizing chamber (Dong and Baer, 2010) This system is very stable and well adapted for humidity range  
71 between 2,500 and 25,000 ppmv (Aemisegger et al., 2012).

72 Several home-made water vapor injection systems have been developed with the specific aim to achieve  
73 a better stability of the generated humidity at low humidity levels. A first approach is to use a dew point  
74 generator injecting small amounts of water into dry air (Lee et al., 2005; Wang et al., 2009). This approach  
75 is time consuming to reach equilibrium and relies on a very precise knowledge of the temperature to  
76 calculate the isotopic fractionation. A method using a piezoelectric microdroplet generator into a dry air  
77 stream could generate water mixing ratios at humidity levels between 12 and 3,500 ppmv (Iannone et al.,  
78 2009; Sturm and Knohl, 2009). However, adjustment of humidity level and long-term stability were difficult  
79 to obtain with such devices. Systems relying on the use of syringe pumps were also built by Gkinis et al.  
80 (2010) and Tremoy et al. (2011): a small fraction of the input stream of liquid water is introduced into a  
81 hot oven where water is vaporized in the presence of a dry air flow. These systems cover humidity range  
82 between 2,000 and 30,000 ppmv. Finally, bubbler systems, in which dry air flows through a large volume  
83 of water to create saturated vapor, are very robust but can only produce water vapor at high humidity  
84 level (Ellehoj et al., 2013). The aforementioned devices are unfortunately not well suited for automatic  
85 long-term operation at low humidity levels. During the 2014-2015 summer field season at Concordia  
86 station in Antarctica, a home-made humidity generator specifically designed for low humidity levels  
87 (Landsberg, 2014) has been deployed (Casado et al., 2016). The device used dual high-precision, low-  
88 volume, syringe pumps to generate stable humidity levels at two different isotopic compositions over the  
89 range from 100 to 800 ppmv (Casado et al., 2016). Unfortunately, we observed quite a large scattering  
90 among the isotopic values measured at similar humidity levels, as well as a large discrepancy between the  
91 humidity dependency of the water isotopic ratios measured in the field and that measured in the  
92 laboratory. Upon return to the laboratory, these defaults were traced primarily to tiny leaks in the water  
93 supply lines to the syringes.

94 Therefore, we re-engineered the prototype by Landsberg (2014) in order to develop a robust and  
95 autonomous device for stable low level humidity generation for the purpose of precise humidity  
96 calibration of spectroscopic instruments. This device has now been operating with minimum manual  
97 intervention for more than one year at two polar stations in Antarctica, Dumont d'Urville and Concordia,  
98 coupled to Picarro laser spectroscopy instruments. We detail here the technical description of the  
99 instrument and show key performance characteristics, enabling, for instance, a discussion of small  
100 amplitude signals such as the diurnal variability of the water vapor isotopic composition in remote dry  
101 sites in East Antarctica.

102

## 103 **2. New vapor generator for low humidity levels**

104

105 The low-humidity level generator (LHLG) developed here relies on the same principle as the one developed  
106 by Landsberg (2014), i.e., a steady, undersaturated evaporation of a liquid water droplet at the tip of a  
107 needle into a dry air stream inside a small evaporation chamber. Based on this first prototype, the  
108 instrument has been remodeled including a specific hardware and software design.

109

### 110 2-1-Physical principle

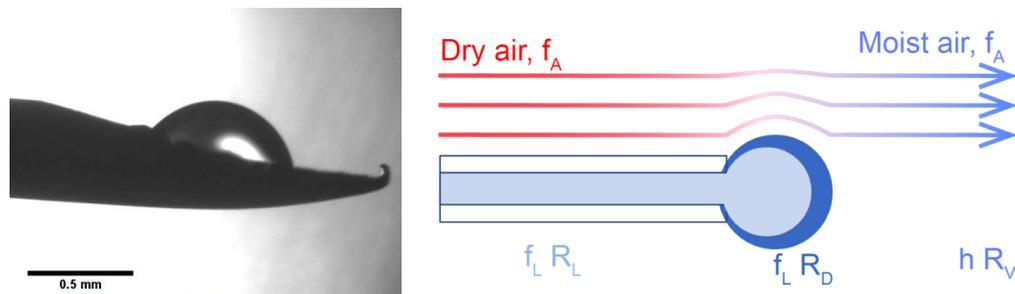

111 The LHLG is based on undersaturated evaporation of a small droplet at the tip of a needle (Figure 1). Liquid  
112 water is pushed through a needle around which dry air is flowing. Dry air is obtained from a bottle of high  
113 purity synthetic air with pressure regulation through two manometers connected in series. The mass flux  
114 of water  $f_L$  is kept low compared to the air mass flow  $f_A$  so that the relative humidity  $h$  of the downstream  
115 moist air flow remains low ( $h < 0.1$ ). Therefore, the air stays largely undersaturated and its humidity is  
116 controlled only by the flow of liquid water in the needle and that of the dry air upstream of it. The mixing  
117 ratio (or humidity) of the air as classically provided by a Picarro instrument is given by:

118

$$119 \quad MR = \frac{d_{H_2O} \times f_L \times R \times T_{st}}{f_A \times P_{st} \times M_{H_2O}} \quad (1)$$

120

121 where  $d_{H_2O} = 1000 \text{ kg.m}^{-3}$  is the density of water,  $R = 8.314 \text{ J mol}^{-1} \text{ K}^{-1}$  is the universal gas constant,  $T_{st} =$   
122  $293.15 \text{ K}$  and  $P_{st} = 1.0.10^5 \text{ Pa}$  are standard conditions of temperature and pressure and  $M_{H_2O} = 18.10^{-3}$   
123  $\text{kg.mol}^{-1}$ . Note that the flow of water  $f_L$  needs to be expressed in  $\text{m}^3.\text{min}^{-1}$  and the air flow  $f_A$  is expressed  
124 in  $\text{m}^3.\text{min}^{-1}$  at  $20 \text{ }^\circ\text{C}$  and  $1 \text{ atm}$  (standard cubic meter per minute).

125

126 **Figure 1:** Evaporation of a droplet in the humidity generator chamber: left, picture from the prototype from  
127 Landsberg (2014); right, schematics of the water molecules being transferred to the air flow (Casado,  
128 2016).

129

130 Physically, when the flux of water or air is changed, there is first a transient regime during which the radius  
131 of the droplet changes, modifying the evaporative surface and therefore the humidity of the outgoing air.

132 Once a stationary regime is reached, the radius of the droplet is stabilized and the humidity is given by  
133 equation 1. In this regime, there is no accumulation of water molecules in the system and therefore the  
134 isotopic composition of the vapor produced is equal to the isotopic composition of the liquid water  
135 injected in the needle:  $R_v = R_L$  (note that because of the fractionation during the transition phase, the  
136 isotopic composition of the droplet  $R_D$  is necessarily different from  $R_L$  and  $R_v$  When changing the flux of  
137 evaporating water, we modify the size of the evaporating surface and therefore the radius of the drop.  
138 The evolution of the radius of the drop can be obtained from the resolution of a non-linear differential  
139 equation of the volume  $V$  of the drop:

140

$$141 \quad dV/dt = f_L - f_{evap} \quad (2)$$

142

143 where  $f_{evap} = k_e \times S$  is the evaporation flux depending of  $k_e$ , the evaporation rate and  $S$ , the surface area of  
144 the drop exposed to the dry air. A good approximation is to consider the shape of the drop as a fraction of  
145 a sphere of variable radius intercepted by the surface of a disk of constant radius (the syringe tip). By  
146 solving numerically the differential equation (2), it is possible to faithfully simulate the behavior of the  
147 device under changing conditions. The isotopic composition is computed by the introduction of an  
148 evaporation fractionation factor following Cappa et al. (2003). This numerical approach validates the  
149 theoretical explanation of the undersaturated evaporation of the droplet. It is noted that in steady-state,  
150 the isotopic composition of the generated water vapor does not depend on the injected flux of water, nor  
151 on the specific humidity.

152

## 153 **2-2- Instrument conception**

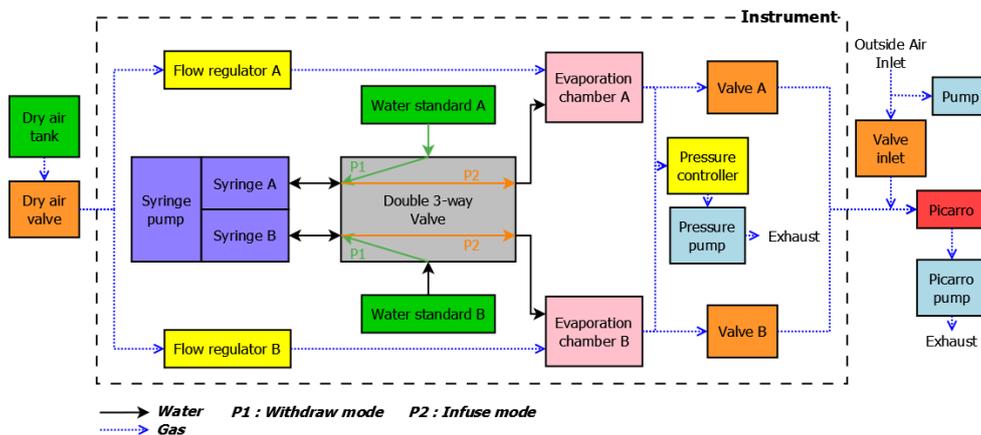

154

### 155 - **Technical realization**

156 As the LHLG relies on operating in a stationary regime, it is important that the dry air input and the water  
157 input are steady. Thus, the air and water fluxes, as well as the air pressure in the evaporation chamber are  
158 controlled by electronic PID regulators. The dry air flux is regulated by a high-precision mass flow controller  
159 (Vögtlin GSC-A9TS-DD22) operating at a range from 6 to 600 sccm ( $\text{std cm}^3 \text{ min}^{-1}$ ) and an accuracy of 3.3  
160 sccm. The water flux is regulated by a high-precision syringe pump (Harvard Apparatus Pump 11 Pico Plus  
161 Elite Dual), which can produce a water flow down to  $10.8 \text{ pL min}^{-1}$  with an accuracy of 0.35 % using syringes  
162 with a volume ranging from  $10 \text{ }\mu\text{L}$  to  $250 \text{ }\mu\text{L}$ . We operate in the routine mode with a dry air flow of 300  
163 sccm and a water flow between  $0.02$  to  $0.5 \text{ }\mu\text{L min}^{-1}$  using mainly  $50$  or  $100 \text{ }\mu\text{L}$  syringes. A single pump is  
164 equipped with two syringes that provide two water flows into two evaporation chambers in parallel  
165 (Figures 2 and 3). Each syringe is connected to a water reservoir and to an evaporation chamber by a  
166 double 3-way liquid valve (Rheodyne MXX777603) switching from an “infuse” mode to a “refill” mode.

167 A major change to the instrument designed by Landsberg (2014) is the introduction of this double 3-way  
168 valve with leak tight connections and an internal volume of 1.9  $\mu\text{L}$ . This modification is an important  
169 improvement as it enables automatic handling of the standards from a reservoir to the evaporation  
170 chamber with a robust connection, avoiding in particular potential air bubbles in the water flow. Indeed,  
171 the compressibility of air bubbles trapped in the water flow can lead to flow irregularities by amplification  
172 of small non-linearities in the progression of the syringe plunger. This will lead to non-steady state  
173 operation, which in turn creates artefacts in the humidity and isotopic composition, reducing the  
174 performance of the calibration device. In addition, the 3-way valve provides the opportunity of a "refill"  
175 mode in which the syringes draw standard water from a reservoir. When equipped with 100- $\mu\text{L}$  syringes,  
176 the instrument can operate for several hours up to one day between refills. With the addition of the auto-  
177 refill option and the effective suppression of bubbles, the instrument can be used unattended for many  
178 months, as required for an Antarctic winter field campaign.  
179

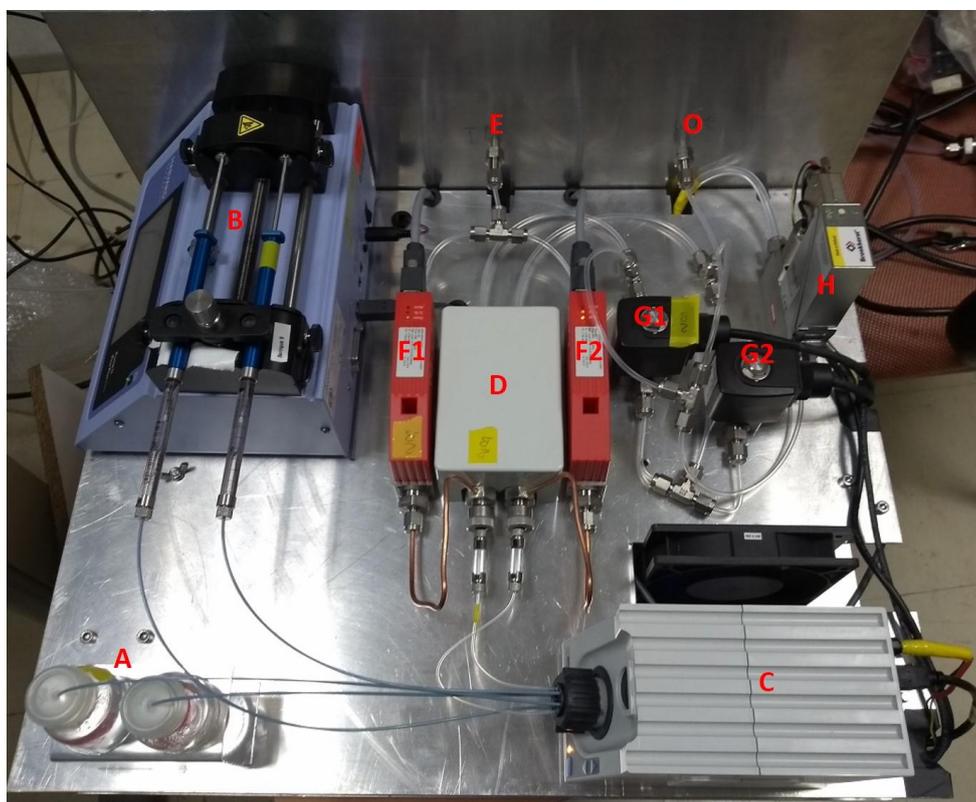

180  
181 **Figure 2:** Humidity generator schematic diagram

182  
183 The evaporation chambers are stainless steel cylinders equipped with specific connectors (Swagelok Ultra-  
184 Torr SS-4CD-TW-25) holding silicon rubber septa through which needles are inserted toward the middle of  
185 the chamber. The pressure in both chambers is regulated by a pressure controller (Bronkhorst P-702CV-  
186 1K1A-AAD-22-V) with a precision of 3 mbar in a range from 0 to 1,000 mbar. This pressurization of the two  
187 chambers combined with the relatively high flow (higher than required by the infrared spectrometers)  
188 enables maintaining a steady state whether or not the infrared spectrometer is connected, and increases  
189 the time efficiency of calibration procedures. The control of the instrument is ensured by a Raspberry Pi  
190 that can be interfaced to the L2130-i in sequencer mode (see below).

191 The hardware has been designed to meet the specifications dictated by field conditions: 1) All components  
192 are fixed in a transportable case (except the dry air bottle), isolated from vibration by an anti-vibration  
193 foam. 2) A panel of connectors (HDMI, USB, Ethernet, etc.) ensures the accessibility to the instrument  
194 when it is closed. 3) The electrical and electronic parts (e.g. power supply, Raspberry Pi) are separated  
195 from the rest of the instrument (e.g. sensors, gauges). Both the electrical and electronic parts are fully and  
196 easily accessible in case of failure.

197  
198 **Figure 3:** Picture of the upper stage of the instrument with the main fluidic parts. Two water standards (A);  
199 a dual syringe pump (B); a double three-way valve (C); two evaporation chambers (D); an input of dry air  
200 (E); two high-precision mass flow controllers (F1 & F2); two electrovalves (G1 & G2); a pressure controller  
201 (H); an outlet (O).

202

203 - **Software details**

204 The control software has been developed using open source Python libraries and homemade drivers,  
205 including a user interface displaying the state of relevant components and the value of the different  
206 sensors. The software (HumGen) can be downloaded on line (<https://github.com/ojsd/humgen>;  
207 <https://doi.org/10.5281/zenodo.4003465>).

208 The LHLG can operate in eight different states, each state representing a specific setup for each element  
 209 (valves position, syringe pump infusion rate, dry air flow rate, pressure). Those eight states can be divided  
 210 into three categories: a simple mode, an expert mode and a humidity dependence calibration mode. The  
 211 simple mode is composed of six predefined states referring to the classical isotopic calibration in everyday  
 212 routine operation (Table 1): 1) measurement of the outside air water vapor isotopic composition; 2) drying  
 213 of the cavities; 3) “humidity boost”, in order to reach faster the desired humidity level in the cavities; 4)  
 214 injection of the standard A in the corresponding evaporation chamber at a set humidity level; 5) injection  
 215 of the standard B in the corresponding evaporation chamber; 6) refill of the syringes. The expert mode is  
 216 useful to adjust each parameter manually: flow rates on the controllers F1 and F2, opening of the  
 217 electrovalves G1 and G2, mode (injection or refill) and infused rate for the syringe pump, pressure  
 218 regulation, state of the double three-way valve, activation of the vacuum pump at the exhaust, opening  
 219 of external electrovalves from the dry air tank and to the inlet (Figures 2 and 3). The humidity dependence  
 220 calibration mode produces a scale of increasing humidity steps in the evaporation chambers (e.g. from 100  
 221 ppmv to 1000 ppmv, through steps of 100 ppmv for 50 minutes for each standard). The details of the  
 222 sequence (standard type, humidity level and duration of each step) is defined in a text file by the operator  
 223 from the Raspberry interface, the Raspberry being itself connected to Ethernet for remote access.  
 224 The L2130-i analyser has an External Valve Sequencer, which is able to turn on/off up to six electrovalves  
 225 and create loop sequences with defined durations for each step of the sequence. This tool can be diverted  
 226 from its original purpose by using it as a 6-digit code: each of the humidity generator’s state is associated  
 227 with a code. When the Picarro’s Valve Sequencer matches one of the state’s code, this state is triggered  
 228 on the humidity generator. This eases both the operator’s activities and the data post-treatment, because  
 229 the current valve status - thus the calibration instrument state - is saved in the analyzer output data file,  
 230 in the "ValveMask" column. The Raspberry inside the LHLG reads the Valve Sequencer state code using  
 231 the Picarro's Remote Control Interface (a RS232 serial connection through one of the rear-face DB9  
 232 connector).

233

States (min)	Flow F1 (sccm)	Flow F2 (sccm)	Valve G1	Valve G2	Syringe Pump ( $\mu\text{L}/\text{min}$ )	Inlet Valve *	Dry air valve	Pressure controller (mbar)	Pressure Pump for exhaust	Double 3-way valve
Outside air (1100)	0	0	Closed	Closed	0	Open	Closed	Off	Off	To chamber
Drying (20)	400	400	Open	Open	0	Closed	Open	Off	Off	To chamber

Boost (0.7)	300	300	Open	Open	Infuse at 2.5	Closed	Open	905	On	To chamber
Standard A (50)	300	150	Open	Closed	Infuse at 0.25	Closed	Open	905	On	To chamber
Standard B (50)	150	300	Closed	Open	Infuse at 0.25	Closed	Open	905	On	To chamber
Reset (1)	Closed	Closed	Closed	Closed	Withdraw max speed	Open	Closed	Off	Off	From standard

234 **Table 1:** Typical routine sequence of measurements + calibration for two standards A and B at 1000 ppmv  
 235 for a measurement site located at sea level.

236 Note that the humidity dependence mode and the expert mode can also be included in the valve sequencer  
 237 but are not used in a daily calibration routine. \*) The Inlet Valve is placed outside the vapor generator  
 238 instrument; when open it enables the measurement of outside air.

239

240 A set of tools has been developed to quickly check daily calibration. In the field, analyzer and LHLG data  
 241 are archived daily and sent to the laboratory, i.e. at LSCE, Gif sur Yvette. They are checked semi-  
 242 automatically once a week to warn maintenance personnel in the event of a malfunction.

243

### 244 3- Performance of the instrument

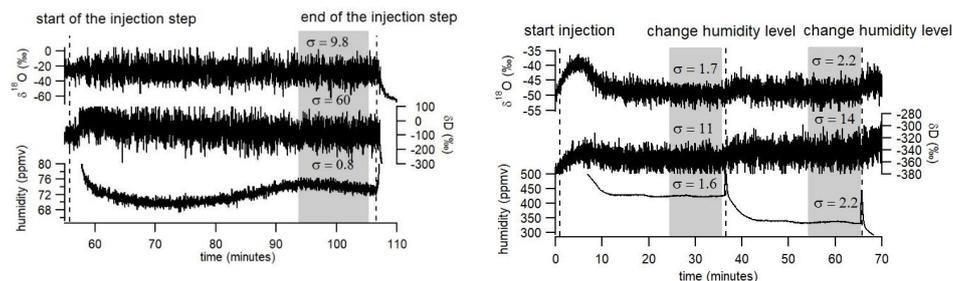

245 The LHLG is able to generate stable levels of humidity ranging from 70 ppmv to 2300 ppmv.

#### 246 3-1- No fractionation during water vaporization in the cavity

247 We have checked that there was no fractionation of the water during its transfer from the bottles to the  
 248 the syringe pump, then from the syringe to the moist air generated in the vaporization chamber. The  
 249 isotopic composition of three different standards have been compared, generated by the present LHLG as  
 250 well as the commercial SDM, both at a humidity of 2,000 ppmv over 40-min time spans. The measured  
 251  $\delta^{18}\text{O}$  and  $\delta\text{D}$  excess values agreed to within 0.2‰ and 1‰, respectively, for the 3 standard waters. Note  
 252 that 2,000 ppmv is close to the upper value of the present LHLG (2,300 ppmv) while it is the very low one  
 253 of the SDM (see Fig. 6 of section 3-2).

254

#### 255 3-2- Stability of the water vapor delivery

256 **Figure 4:** Records of  $\delta^{18}\text{O}$ ,  $\delta\text{D}$  and humidity over 3 humidity plateaus (72 ppmv on the left, 425 and 335  
257 ppmv on the right) obtained with the LHLG (December 2018 at Concordia). The grey rectangles indicate the  
258 period (10 min) over which the average values are kept for calibrating the data generated by the L2130-i  
259 analyzer.

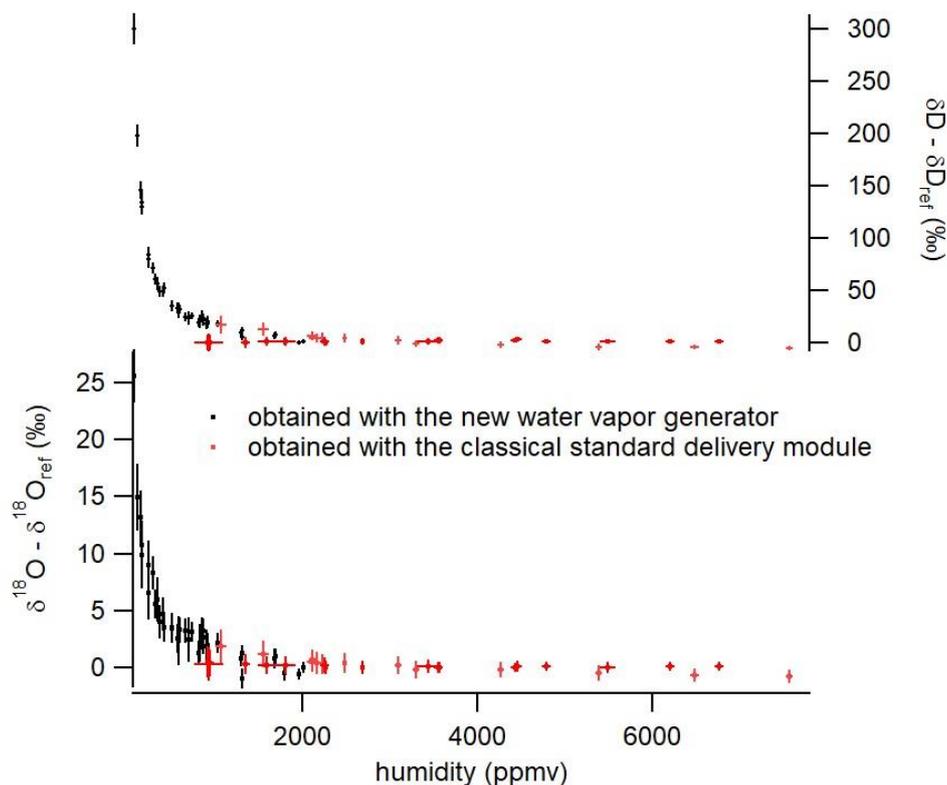

260

261 Figure 4 displays the performance of the instrument at different low humidity levels (72, 425, and 335  
262 ppmv). In the routine mode, we select the last 10 minutes before the following switch of the instrument  
263 to measure the average level of humidity and the isotopic ratios,  $\delta^{18}\text{O}$  and  $\delta\text{D}$ . We also calculate the  
264 associated standard deviations and reject the values if the humidity standard deviation exceeds 30 ppm  
265 over these last 10 minutes. In Figure 4, one observes that the standard deviations for humidities generated  
266 are actually much lower, in the 2 ppm range. The corresponding standard deviations for the isotopic ratios  
267 ( $\delta^{18}\text{O}$  and  $\delta\text{D}$ , see values indicated in Figure 4) increase with decreasing humidity, reflecting the molecular  
268 absorption signal decrease recorded by the Li2130-i laser analyzer. This has an obvious impact on the  
269 determination of the relationship between humidity and water vapor isotopic composition.

270 The performance of the present LHLG can be compared to the performance of the SDM. For such  
271 comparison, we used daily calibrations performed with a SDM, in a routine mode, during a 4.5 years field  
272 deployment in Svalbard (Leroy-Dos Santos et al., 2020). Over the full series, we kept only the 10-minute  
273 plateaus where standard deviation associated with humidity variations during calibration was below 150  
274 ppmv. The best result at low humidity over the full period was a standard deviation  $\sigma$  of 31 ppmv over 10  
275 minutes at 500 ppmv. Standard deviation largely increases when humidity decreases. This best SDM  
276 performance is significantly below the performance of the LHLG, which is a standard deviation 1- $\sigma$  lower  
277 than 10 ppm on average and a 1- $\sigma$  of 2 ppm for 30% of the generated humidity plateaus.

278

279 **3-3- Determination of the influence of humidity on water vapor isotopic composition**

280

281 **Figure 5:** Influence of humidity on the isotopic composition ( $\delta^{18}\text{O}$  and  $\delta\text{D}$ ) of the vapor obtained with a SDM  
282 (red) and with our new LHLG (black). The error bars are calculated as the standard deviation ( $1\sigma$ ) over the  
283 generated values by the L2130-i instrument at 1 second resolution (i.e. without any pre-averaging of the  
284 raw dataseries). The  $\delta^{18}\text{O}_{ref}$  and  $\delta\text{D}_{ref}$  are the true values of the injected water standards.

285

286 Contrary to the commercial SDM, which hardly produces stable and reproducible humidity levels below  
287 500 ppmv, the LHLG was able to daily produce stable 10-minute humidity plateaus over the range from 70  
288 ppmv to 2,000 ppmv with an associated standard deviation lower than 10 ppmv over more than one year  
289 at the Concordia station (installation in December 2018). The stability of the LHLG allows a robust  
290 quantification of the L2130-i analyzer drift thanks to a daily measurement of the same water isotopic  
291 standard reference (Table 2). It also permits the characterization of the measurement nonlinearities  
292 observed at low humidity (Figure 5). The more than one-year long Concordia dataset showed that the  
293 humidity dependence of  $\delta^{18}\text{O}$  and  $\delta\text{D}$  did not vary measurably. The uncertainty of the obtained calibration  
294 curve can be attributed entirely to the L2130-i  $\delta^{18}\text{O}$  and  $\delta\text{D}$  measurements. In other words, the uncertainty  
295 bars in the horizontal (x-) axis for the black curve in Fig. 5, associated with the LHLG, are negligible.

296

Date	Humidity (ppmv)	$\delta^{18}\text{O}$ (‰)	$\delta\text{D}$ (‰)
16 December 2019	380	-32.0	-207
17 December 2019	369	-31.9	-210
23 December 2019	371	-31.7	-212
24 December 2019	367	-31.9	-211
25 December 2019	378	-31.7	-211
26 December 2019	370	-31.7	-209
27 December 2019	386	-32.3	-208
28 December 2019	370	-31.5	-211
29 December 2019	364	-31.5	-209
30 December 2019	380	-31.7	-211
31 December 2019	372	-31.8	-211
1 January 2020	379	-31.8	-212
2 January 2020	371	-31.7	-211
3 January 2020	381	-31.6	-210
4 January 2020	378	-31.6	-210
5 January 2020	371	-31.6	-208

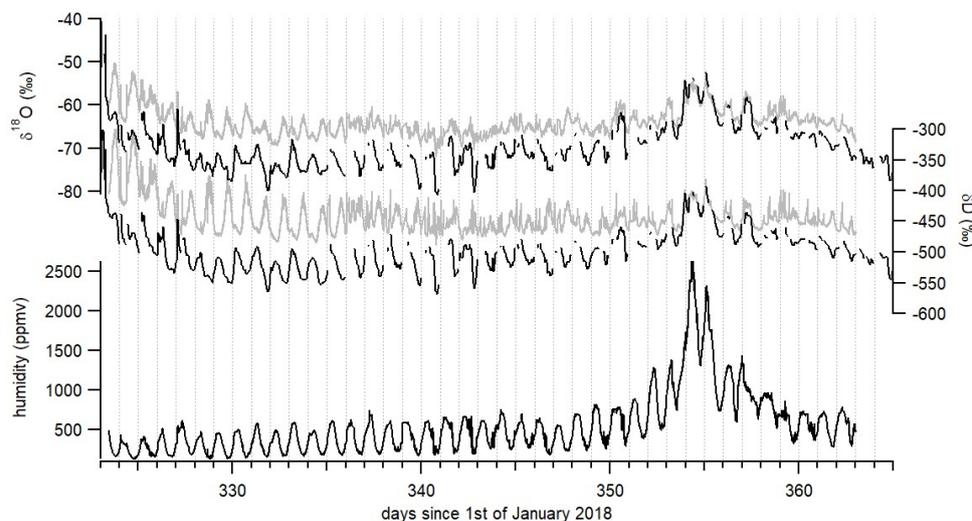

297

298 **Table 2:** Example of daily measurements of humidity ( $1\sigma$  over 10 minutes = 9 ppmv),  $\delta^{18}\text{O}$  ( $1\sigma$  over 10  
299 minutes = 1.4 ‰), and  $\delta\text{D}$  ( $1\sigma$  over 10 minutes = 4.5 ‰) of a laboratory standard (NEEM) using the LHLG  
300 at low humidity during the austral summer of 2019-2020.

301

#### 302 **4- Application**

303 The main application of this device is the interpretation of water isotopic profiles at dry sites, in particular  
304 in polar regions. As shown in Figure 5, the influence of humidity on the measurement of the water vapor  
305 isotopic composition with the L2130-i analyzer is large when humidity is below 2,000 ppm and increases  
306 when humidity decreases. Even though the precise isotope ratio-humidity calibration curve is likely to be  
307 different from one analyzer to another, all laser-based water isotope analyzers investigated to date have  
308 shown a strongly non-linear response at low humidity levels (Guilpart et al., 2017; Leroy Dos-Santos, 2020;  
309 Weng et al., 2020). At the Concordia station, even in summer, humidity is generally below 1000 ppm  
310 (Figure 6) so that the interpretation of the diurnal variability of the water vapor isotopic composition is  
311 strongly affected by the dependency of the measured  $\delta^{18}\text{O}$  and  $\delta\text{D}$  signals on humidity. Figure 6 displays  
312 such diurnal variabilities during austral summer 2018-2019 at Concordia and the consequently large  
313 correction of the isotopic records (uncorrected in grey and corrected in black).

314

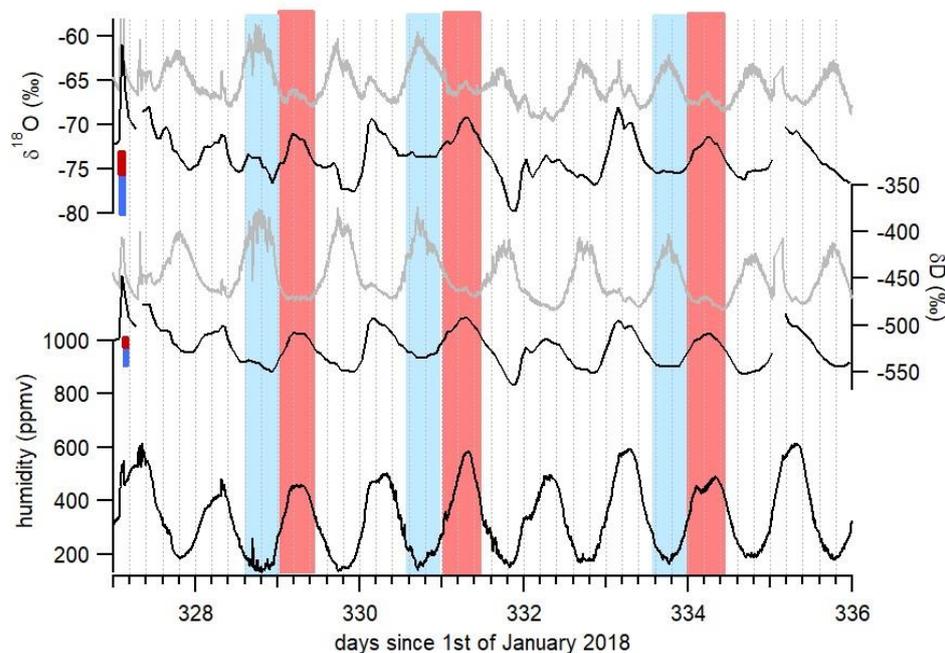

315 **Figure 6:**  $\delta^{18}\text{O}$ ,  $\delta\text{D}$  and humidity records over December 2018 and beginning of January 2019. Raw isotopic  
316 values are in grey. Corrected isotopic values at hourly resolution are in black after correction of the  
317 influence of humidity on the water isotopic ratios and removal of measurements performed during  
318 calibration or other maintenance operations.

319

320 The data clearly demonstrate the importance of the humidity correction which shifts the curves generally  
321 to lower isotopic ratio values. However, the difference between uncorrected and corrected data is  
322 particularly important in the observation of the diurnal variability, illustrated even better when zooming  
323 in on a section of the data, as in Figure 7. When looking in detail at the diurnal variability in the raw  $\delta^{18}\text{O}$   
324 and  $\delta\text{D}$  isotope data, some periods stand out with two daily peaks identified, one in phase with the  
325 humidity peak (marked in red in Figure 7) and one occurring during the period of minimum humidity  
326 (marked in blue in Figure 7). The strong non-linearity of the calibration curve of Figure 5 suggests that  
327 artificial peaks in  $\delta^{18}\text{O}$  and  $\delta\text{D}$  could be due to changing humidity levels. Indeed, after correcting the data  
328 for the humidity dependence of the analyzer (black curve in Figure 7), the isotopic peaks occurring during  
329 humidity minima are diminished or disappear altogether, while the peaks occurring during humidity  
330 maxima are amplified. More strikingly, the phase of the signal changes by practically  $180^\circ$  over some  
331 periods. Whereas the raw isotope signal peaks during the night, the corrected record shows higher isotope  
332 ratios during daytime. The diurnal variability recorded on both raw and corrected isotopic values during a  
333 period with higher humidity level, hence when the isotope ratio-humidity correction is smaller (around  
334 day 355 in figure 6), also shows that the  $\delta^{18}\text{O}$  ( $\delta\text{D}$ ) diurnal cycles are indeed in-phase with the humidity  
335 cycle. This result confirms the correlation between humidity cycles and  $\delta^{18}\text{O}$  and  $\delta\text{D}$  of the water vapor at  
336 the daily scale at Concordia as reported by Casado et al. (2016). We thus conclude that the anticorrelation

337 observed between  $\delta^{18}\text{O}$  ( $\delta\text{D}$ ) and humidity in the raw data (highlighted in blue in Figure 7) during periods  
338 of low humidity is an artefact due to the influence of the humidity level on the vapor isotopic  
339 measurements by the L2130-i analyzer.

340  
341 **Figure 7:** Focus on diurnal variability of  $\delta^{18}\text{O}$ ,  $\delta\text{D}$  and humidity recorded at Concordia. Grey curves show the  
342 raw measurements and black curves the corrected records. The red (blue) bars indicate the calculated  
343 uncertainty due to the isotopes vs humidity dependence (Figure 5) on the corrected  $\delta^{18}\text{O}$  and  $\delta\text{D}$  values  
344 during periods with maximum (minimum) humidity. The red (blue) rectangles indicate half day with  
345 maximum (minimum) humidity.

346

## 347 5- Conclusion

348 We have developed an autonomous instrument for low humidity generation (70 to 2,300 ppmv) with  
349 controlled water vapor isotopic composition specifically aiming at carrying out continuous measurements  
350 of the water vapor isotopic composition using a laser-based spectrometer in regions characterized by very  
351 low humidity, such as polar regions. An interface permits to conveniently connect the new LHLG to the  
352 valve sequencer port of commercial Picarro instruments. After more than one year of routine operation  
353 on two Antarctic sites (Dumont d'Urville and Concordia), this instrument has proven to be very reliable  
354 and robust. It consistently generates stable humidity levels with a  $1\sigma$  variability lower than 10 ppm over  
355 more than 10 minutes. Besides, its performance is significantly better than that of the Picarro SDM at low  
356 humidity.

357 We used this instrument for the calibration of our water isotopic data with a special focus on accurately  
358 quantifying the influence of humidity on the measured isotopic composition of the water vapor. This effect  
359 is huge at low humidity. We showed that this has an important impact on the interpretation of the diurnal  
360 cycles of  $\delta^{18}\text{O}$  and  $\delta\text{D}$  in the water vapor at the Concordia station at humidity below 1,500 ppmv. We were  
361 able to confirm that, at this site, the diurnal  $\delta^{18}\text{O}$  and  $\delta\text{D}$  variability is actually correlated with humidity  
362 variability, which would not have been possible without the new LHLG instrument.  
363 Finally, the development of such an instrument is an important step forward to a better understanding of  
364 the transfer function between climate parameters and the isotopic composition of deep ice cores from  
365 the remote East Antarctic plateau, especially in the context of the new program “Beyond EPICA”. It should  
366 be completed by ongoing development of laser spectrometers better adapted to low humidity levels, such  
367 as those based on the technique of Optical Feedback Cavity Enhanced Absorption Spectroscopy (OFCEAS)  
368 (Casado et al., 2016; Landsberg, 2014; Landsberg et al., 2014).

369

#### 370 **Author contributions**

371 CLDS, MC, FP and EK designed and built the instrument. OJ realized the software interface development.  
372 CLDS, MC and AL installed the instrument in Antarctica and tested it extensively. EK, SK and EF tested the  
373 instrument in the laboratory. AL wrote the manuscript with the help of all co-authors.

374

#### 375 **Acknowledgments**

376 The development presented in this manuscript is largely inspired from the initial PhD work of Janek  
377 Landsberg which we gratefully acknowledge here. The research leading to these results has received  
378 funding from the Antarctic Snow program of the Fondation Prince Albert II de Monaco, the ANR EAIIST and  
379 CNRS-LEFE program ADELISE. The deployment of this instrument in the field was made possible through  
380 the logistic support of the NIVO2 & ADELISE IPEV programs.
