1. Calculation of X_R

Due to the variation of reagent ion source and sample humidity, the pyrrole (C_4H_5N) ion signal is normalized to a standard reagent ion signal of 10^6 counts/s (cps) as following in Eq. 1.

$$Pyrrole_{ncps} = \frac{i[C_4H_5NH^+] \times 10^6}{i[H_3O^+] + X_R \times i[H_3O^+H_2O]} \quad (1)$$

Where $Pyrrole_{ncps}$ is a normalized signal of the pyrrole, and $i[C_4H_5NH^+]$, $i[H_3O^+]$, and $i[H_3O^+H_2O]$ represent the signals of different product ions, respectively. The value of X_R not only represents difference in detection efficiencies of detector, but also the difference in rate coefficients of the proton transfer reactions $H_3O^+ + \text{pyrrole}$ and $H_3O^+(H_2O) + \text{pyrrole}$ (de Gouw et al., 2003; de Gouw et al., 2007).

Here, the X_R value of pyrrole was determined by the laboratory experiment. The $i[C_4H_5NH^+]$, $i[H_3O^+]$, and $i[H_3O^+H_2O]$ were measured from a dry (0%) to 100% humidified pyrrole standard gas, respectively. The pyrrole signal become independent of relative humidity when normalized to $i[H_3O^+] + X_R \times i[H_3O^+H_2O]$. In other words, the correlation coefficient (r^2) of relative humidity and normalized pyrrole signal reaches a minimum at the optimized X_R value. This method is inspired by the calculation of enhancement ratios and the source contribution of different species in the previous studies (Millet et al., 2005; Yuan et al., 2010). Figure S1 (a) shows the result of the correlation coefficient of at different X_R with a bin of 0.01 values. We found that r^2 is the smallest when the X_R value is 0. Figure S1 (b) shows the time series of pyrrole signals before and after normalizing to $i[H_3O^+] + X_R \times i[H_3O^+H_2O]$, respectively. It is shown that pyrrole signal reaches a stable level after normalized with the increase of relative humidity. Therefore, the X_R value is determined as 0.

Table S1. The list of all species used to calculate OH reactivity in this study.

Species name	Species name	Species name
Alkanes	n-Undecane	1,2,3-Trimethylbenzene
Ethane	n-Dodecane	p-Diethylbenzene
Propane	Alkenes	m-Diethylbenzene
iso-Butane	Ethene	Alkyne
n-Butane	Propene	Acetylene
iso-Pentane	cis-2-Butene	OVOCs
n-Pentane	trans-2-Butene	Formaldehyde
Cyclopentane	1-Butene	Methanol
2-Methylpentane	1-Pentene	Acetaldehyde
n-Hexane	Isoprene	Ethanol
Cyclohexane	cis-2-Pentene	Acrolein
2,2-Dimethylbutane	trans-2-Pentene	Acetone
2,3-Dimethylbutane	1-Hexene	Propanol
3-Methylpentane	Aromatics	Furan
3-Methylhexane	Benzene	MVK+MACR
2,2,4-Trimethylpentane	Toluene	MEK
Methylcyclopentane	Ethylbenzene	Pentanones
n-Heptane	x, p-Xylene	Phenol
Methylcyclohexane	Styrene	2-Furaldehyde
2,3,4-Trimethylpentane	o-Xylene	Benzyl alcohol
2-Methylheptane	n-Propylbenzene	Inorganics
3-Methylheptane	isopropylbenzene	CO
2,4-Dimethylpentane	o-Ethyltoluene	NO
2,3-Dimethylpentane	m-Ethyltoluene	NO ₂
2-Methylhexane	p-Ethyltoluene	SO ₂
n-Octane	1,2,4-Trimethylbenzene	O ₃
n-Decane	1,3,5-Trimethylbenzene

49 **Figure S1.** (a) The horizontal represents different X_R values (from -2.5 to 2.5). The
50 vertical represents the correlation coefficient that pyrrole is normalized to H_3O^+ signals
51 and m37/m19 at different X_R values. (b) The time series of the signal of pyrrole in cps
52 (red) and in ncps (yellow, normalized to m19 and m37) with the change of humidity
53 (blue, represented as the ratio of m37 to m19).

Figure S2. The remaining concentrations of pyrrole, NO, NO_2 , HO_2 , and RO_2 outflowing of the reactor (with the reaction time of ~ 11 s) as a function of introduced NO in the reactor.

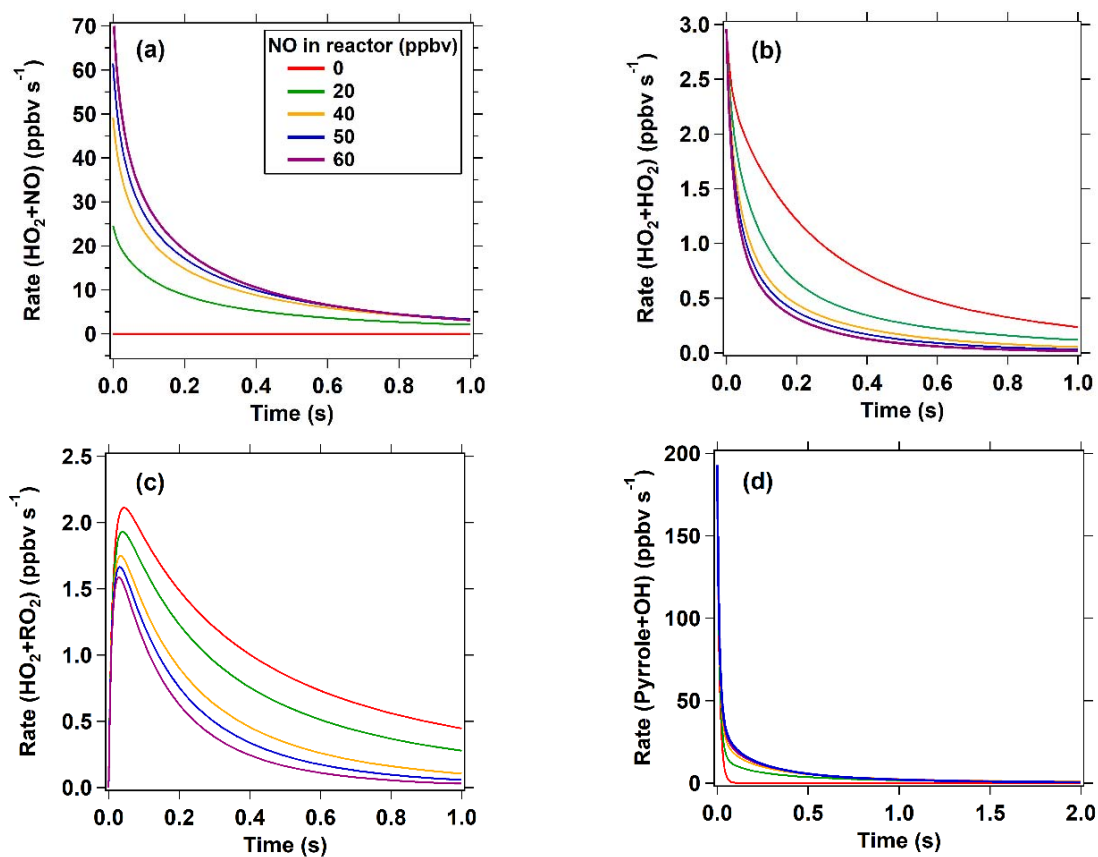

Figure S3. The reaction rates of $\text{HO}_2 + \text{NO}$, $\text{HO}_2 + \text{HO}_2$, $\text{HO}_2 + \text{RO}_2$ and $\text{Pyrrole} + \text{OH}$ as a function of reaction time in the reactor. Four levels of introduced NO concentrations (0, 20, 40, 50, 60 ppbv) was selected. The reaction time ranging from 0 to 1s is displayed due to the high reaction rates mainly occurred during this period.

Figure S4. (a) The OH reactivity calibration of NO_2 , **(b)** Comparison of measured and true OH reactivity of NO_2 at different NO concentrations introduced through arm C in ICRM system.

Figure S5. The corrected measured reactivity (R'_{meas}) using the calibration factor α_3 ($R'_{\text{meas}} = (\frac{1}{\alpha_3} * R_{\text{meas}})$) as a function of NO concentrations at (a) different levels of VOCs reactivity for the same species (propene) and (b) different VOCs species for the same OH reactivity level (10 s^{-1}); (c) The response of the R'_{meas} to NO concentrations at different inorganic species for the same OH reactivity level (10 s^{-1}). The NO, CO, SO₂, and VOCs were introduced into the reactor through arm C.

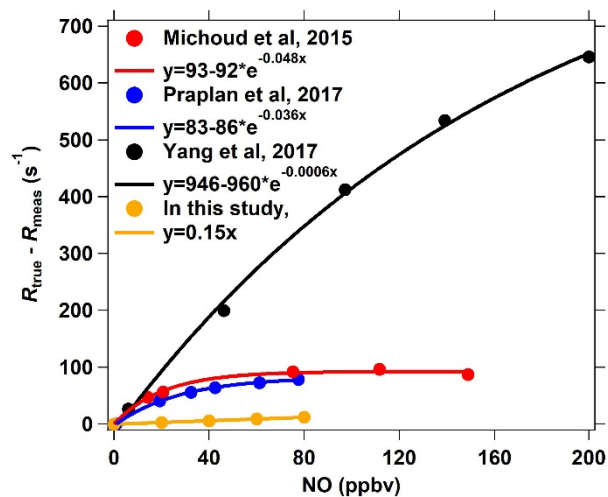

Figure S6. The effect of NO on the difference between true reactivity and measured OH reactivity ($R_{\text{true}} - R_{\text{meas}}$) in the original CRM system. In this study, to correct the systematic deviation at ambient NO=0, the $R_{\text{true}} - R_{\text{meas}}$ is defined as the difference between true OH reactivity (R_{true}) and the corrected measured OH reactivity (R'_{meas}) using the calibration factor α_1 ($R'_{\text{meas}} = (\frac{1}{\alpha_1} * R_{\text{meas}})$).

83

84 **Figure S7.** Linear correlation between measured and true OH reactivity of propane,

85 CO , and SO_2 simulated by box-model.

Figure S8. The variation in pyrrole concentration due to photolysis effect in the ICRM system. Two modes were tested by turning on and off the mercury lamp at dry condition (no humidification).

Figure S9. The daily calibration of measured reactivity during the field campaign at Heshan site. The ratio of R_{meas} to R_{true} ($R_{\text{meas}}/R_{\text{true}}$) of each day is given. The dashed line represents the average value of $R_{\text{meas}}/R_{\text{true}}$ during the measurement. Three VOC standard gases (propane, propene and Toluene) were used for the calibration.
