17 **Abstract.** Solar-induced chlorophyll fluorescence (SIF) is emitted during photosynthesis in plant leaves. It constitutes a
18 small additional offset to reflected radiance and can be observed by sensitive instruments that with high signal-to-noise ratio
19 and spectral resolution. The Chinese global carbon dioxide monitoring satellite (TanSat), as its mission, acquires greenhouse
20 gas column density. The advanced technical characteristics of the hyper-spectrum grating spectrometer (ACGS) onboard
21 TanSat enable SIF retrieval from space observations in the O₂-A band. In this study, one-year SIF data for each sounding
22 was retrieved from Orbiting Carbon Observatory-2 (OCO-2) and TanSat measurements using the IAPCAS/SIF algorithm. A
23 comparison between the SIF results retrieved from OCO-2 spectra and the official OCO-2 SIF product (OCO2_Level
24 2_Lite_SIF.8r) shows their strong linear relationship ($R^2 > 0.85$) and suggests the reliability of the SIF retrieval algorithm.
25 The global distribution showed that the SIF retrieved from the two satellites shared the same spatial pattern for all seasons
26 with the gridded SIF difference less than $0.3 \text{ W m}^{-2} \mu\text{m}^{-1} \text{ sr}^{-1}$, and they also agreed well with the official OCO-2 SIF product
27 with the difference less than $0.2 \text{ W m}^{-2} \mu\text{m}^{-1} \text{ sr}^{-1}$. The retrieval uncertainty of seasonal-gridded TanSat SIF is less than 0.03
28 $\text{W m}^{-2} \mu\text{m}^{-1} \text{ sr}^{-1}$ whereas the uncertainty of each sounding ranges from 0.1 to $0.6 \text{ W m}^{-2} \mu\text{m}^{-1} \text{ sr}^{-1}$. The relationship between
29 annually-averaged SIF products and FLUXCOM gross primary productivity (GPP) was also estimated for six vegetation
30 types in a $1^\circ \times 1^\circ$ grid over the globe, indicating that the SIF data from the two satellites have the same potential in
31 quantitatively characterizing ecosystem productivity. The spatiotemporal consistency between TanSat and OCO-2 and their
32 comparable data quality make the comprehensive usage of the two mission products possible. Data supplemented by TanSat
33 observations are expected to contribute to the development of global SIF maps with more spatiotemporal detail, which will
34 advance global research on vegetation photosynthesis.

35 **1 Introduction**

36 Terrestrial vegetation accounts for a large part of the ecosystem, with its photosynthesis and respiration processes playing
37 important roles in the global carbon cycle. Incoming radiation is absorbed, reflected, and/or transmitted by plant leaves. A
38 portion of the absorbed radiation is used by the chlorophyll in plant leaves for carbon fixation, while the rest is either
39 dissipated as heat or re-emitted as solar-induced chlorophyll fluorescence (SIF) at longer wavelengths (Frankenberg et al.,
40 2011a, 2014). In contrast to the traditional remotely sensed vegetation indices obtained from some studies (Frankenberg et
41 al., 2011b; Guanter et al., 2014; Li et al., 2018; Sun et al., 2017a; Yang et al., 2015; Zhang et al., 2014), SIF offers the
42 potential to measure photosynthesis activity and gross primary production (GPP), due to the strong correlation between these
43 measures (Frankenberg et al., 2011b; Guanter et al., 2012, 2014). The fluorescence emission (Fs) adds a low-intensity
44 radiance less than $10 \text{ W m}^{-2} \mu\text{m}^{-1} \text{ sr}^{-1}$ and fills in the solar absorption features of the reflected spectrum (Frankenberg et al.,
45 2011a). The filling-in effect of the solar lines (Fraunhofer lines) is the basic principle applied to measure SIF from space
46 using the capabilities of hyperspectral observation (Frankenberg et al., 2011b; Guanter et al., 2012).

47 The first attempt at SIF research based on space-based observations was performed using images acquired by the Medium
48 Resolution Imaging Spectrometer (MERIS) onboard the ENVironmental SATellite (ENVISAT) (Guanter et al., 2007). This
49 led to a new idea for conducting SIF studies on a global scale. The first global SIF map was retrieved with high-resolution
50 spectra from the Greenhouse-gases Observing SATellite (GOSAT) (Joiner et al., 2011; Frankenberg et al., 2011b). After that,
51 SIF retrievals were implemented from a variety of satellite measurements, such as those from the Global Ozone Monitoring
52 Experiment-2 (GOME-2) instruments onboard meteorological operational satellites, SCIAMACHY on board ENVISAT, and
53 Orbiting Carbon Observatory-2 (OCO-2) (Joiner et al., 2016; Köhler et al., 2015). The TROPOspheric Monitoring
54 Instrument (TROPOMI) on board Sentinel 5 Precursor (S-5P) provides more efficient SIF observations in terms of global
55 coverage and new opportunities for exploring the application potential of SIF data in the terrestrial biosphere as well as in
56 climate research (Doughty et al., 2019; Köhler et al., 2018b). Furthermore, an upcoming European Space Agency mission
57 called FLuorescence EXplorer (FLEX), the first satellite dedicated to SIF emission observation, will launch in the middle of
58 2024 (Drusch et al., 2017). Many studies on SIF applications have been initiated with the accumulation of SIF products in
59 recent years. The responses of satellite-measured SIF to environmental conditions have been applied to drought dynamics
60 monitoring and regional vegetation water stress estimation (Lee et al., 2013; Sun et al., 2015; Yoshida et al., 2015). As a
61 proxy of photosynthesis, SIF acts as a powerful constraint parameter in estimating carbon exchange in an ecosystem between
62 the atmosphere, ocean, and soil; as such, the analysis of the relationship between SIF and GPP has become an important
63 research topic (Li et al., 2018; Köhler et al., 2018a; Sun et al., 2017a; Zhang et al., 2018). The strong linear relationship
64 between them paves the way for improving terrestrial ecosystem model simulation of GPP, along with consequent
65 improvement of global carbon flux estimation (MacBean et al., 2018; Yin et al., 2020). GPP estimations based on satellite-
66 measured SIF have proven to be an effective method validated by in-situ flux observations (Joiner et al., 2018; Qiu et al.,
67 2020). However, uncertainty in the factors that determine the relationship between SIF and GPP still exists and is a key

68 limitation in the application of SIF to flux estimation. Based on multi-satellite SIF products, eddy covariance flux tower
69 observations, and ecological models, the relationship between SIF and GPP under different environmental conditions has
70 been discussed in a number of studies to analyze the dominant factors for the growing status of different biomes, such as
71 temperature, soil moisture, and vegetation types (Chen et al., 2020; Doughty et al., 2019; Li et al., 2020; Qiu et al., 2020; Yin
72 et al., 2020).

73 The Chinese global carbon dioxide monitoring satellite (TanSat) was launched in December 2016. Aiming at acquiring CO₂
74 concentrations as OCO-2, TanSat flies in a sun-synchronous orbit at approximately 700 km in height with a 16-day repeat
75 cycle and an equator crossing time of ~1:30 p.m. local time (Cai et al., 2014; Liu et al., 2018; Yang et al., 2018). Onboard
76 TanSat, the hyperspectral Atmospheric Carbon-dioxide Grating Spectrometer (ACGS) is designed to separately record solar
77 backscatter spectra in three channels centered at 0.76 μm (O₂-A band), 1.61 μm (weak CO₂ absorption band), and 2.06 μm
78 (strong CO₂ absorption band). With the recorded spectra, many Optimal Estimation Method (OEM) full physics retrieval
79 algorithms have been developed and applied for XCO₂ retrievals (Boesche et al., 2009; Butz et al., 2009, 2011; O'Dell et al.,
80 2012; Reuter et al., 2010; Yang et al., 2015b; Yoshida et al., 2011, 2013). The Institute of Atmospheric Physics Carbon
81 Dioxide Retrieval Algorithm for Satellite Remote Sensing (IAPCAS) algorithm has been applied for TanSat retrieval (Yang
82 et al., 2018; Yang et al., 2021) and was also previously tested on GOSAT and OCO-2 missions (Yang et al., 2015b).
83 However, the fluorescence feature causes substantial biases when retrieving surface pressure and scattering parameters from
84 the O₂-A band, and the associated errors propagate into the XCO₂ retrievals. In previous XCO₂ retrieval, the surface
85 emissions were well modeled as a continuum zero offset of the O₂-A band to reduce errors (Frankenberg et al., 2011a, 2012;
86 Butz et al., 2009, 2010; Joiner et al., 2012). The high spectral resolution of ~0.044 nm and a signal-to-noise ratio of ~360 in
87 the O₂-A band makes it possible to obtain SIF from space measurements, with a spatial resolution of 2 km × 2 km in nadir
88 mode (Liu et al., 2018).

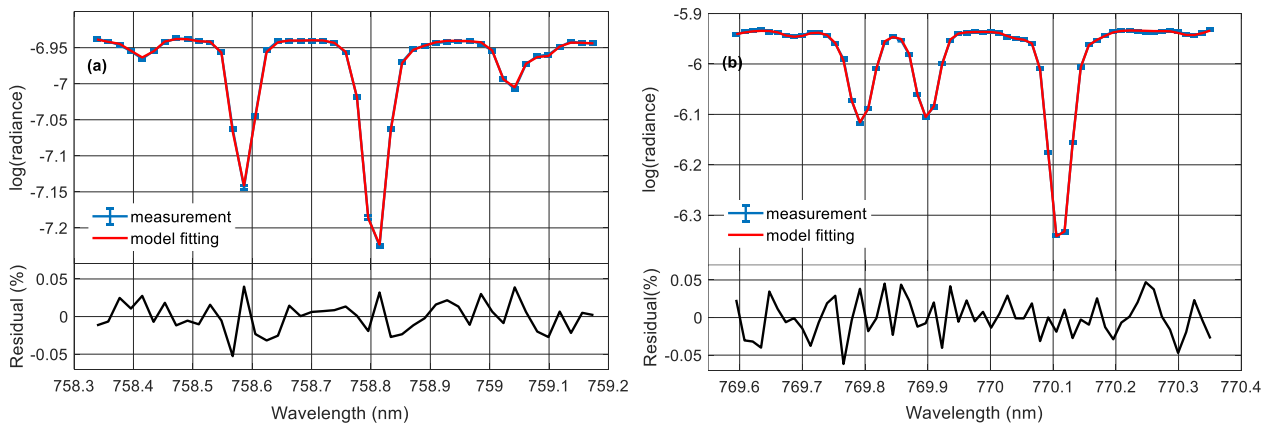

89 Various approaches have been used to infer SIF from satellite measurements (Frankenberg et al., 2011b, 2014a, 2014b;
90 Guanter et al., 2007, 2012, 2015; Joiner et al., 2011, 2013, 2016; Köhler et al., 2015, 2018b). The SIF signal induces a
91 filling-in effect of solar lines, which can be used for SIF retrieval, as the fractional depth of solar Fraunhofer lines does not
92 change during radiation transmission in the atmosphere. To recognize the filling-in features by SIF, high-resolution spectra
93 and an instrument spectral response function (ISRF) are required to describe subtle changes in the spectral absorption lines.
94 With the detailed spectral features, a method was developed based on solar line fitting and the Beer-Lambertian law. This
95 method is robust and accurate when the spectrum is out of the influence of telluric absorptions, even in the presence of
96 aerosols (Frankenberg et al., 2011a; Joiner et al., 2011); in the current study, this method was applied to develop the
97 IAPCAS/SIF algorithm. Another SIF retrieval method is the data-driven algorithm based on the singular value
98 decomposition (SVD) technique (Joiner et al., 2011; Guanter et al., 2012), which has been broadly applied in GOSAT, OCO-
99 2, TanSat and TROPOMI SIF retrieval (Joiner et al., 2011; Guanter et al., 2012, 2015; Frankenberg et al., 2014a; Du et al.,
100 2018; Köhler et al., 2018b). In the data-driven method, the spectrum is represented as a linear combination of the SIF signal
101 and several singular vectors that are trained from non-fluorescent scenes by SVD; thus, the SIF signal can be obtained with

102 linear least-squares fitting (Du et al., 2018; Guanter et al., 2012). The first TanSat SIF map was obtained by the SVD
 103 method (Du et al., 2018). In a previous study, a new TanSat SIF product retrieved by IAPCAS/SIF algorithm was introduced
 104 and the two kinds of TanSat SIF product by IAPCAS/SIF and SVD methods were compared. The preliminary comparison
 105 between the two TanSat SIF products shows that the two SIF products share a similar global pattern and signal magnitude
 106 for all seasons while different biases still exist in four seasons (Yao et al., 2021). The different biases in four seasons may be
 107 caused by the different training samples of the SVD method, which indicates that the training samples have a significant
 108 impact on the retrieval results. In order to obtain stable SIF data products from TanSat and other subsequent satellite
 109 missions, it is particularly important to establish a stable and high-precision SIF inversion algorithm. To detailed validate the
 110 IAPCAS/SIF algorithm and test the potential of comprehensive usage of multi-satellites SIF data in analysis, in this study,
 111 we detailed the TanSat SIF retrieval using the IAPCAS/SIF algorithm and made a comparison of SIF products between
 112 TanSat and OCO-2 in variety of temporal-spatial scales, although a preliminary test was shown in previous work.

113 2 Data and retrieval algorithm

114 2.1 Retrieval Principle and Method

115 We used TanSat version 2 Level 1B (L1B) nadir-mode earth observation data in the retrieval process. The measurements
 116 covered the period from March 2017 to February 2018. Polarized radiance in the O₂-A band with a spectral resolution of
 117 0.044 nm was provided in the L1B data, and two micro-windows near 757 nm (758.3-759.2 nm) and 771 nm (769.6-770.3
 118 nm) were chosen to retrieve the top-of-atmosphere (TOA) SIF while avoiding the contamination from strong lines of
 119 atmospheric gas absorption. The retrieval was independent for each micro-window as shown in Figure 1. To avoid
 120 duplication of information, we use the SIF product at 757 nm as the example in the analysis.

121
 122 **Figure 1: The fitted spectra and residuals for the (a) 757 nm and (b) 771 nm micro-windows of TanSat measurement. The error**
 123 **bar of the measured spectra depicts the estimated precision of each TanSat sounding.**

124

125 Filling-in on solar lines by chlorophyll fluorescence in the O₂-A band can be detected in the hyperspectral measurements
 126 from TanSat. This effect on spectral radiance is different from the impact of atmospheric and surface processes, e.g.,
 127 scattering and absorption. For example, scattering by aerosols and clouds does not change the relative depth of clear solar
 128 lines, unlike the SIF emission signal. We applied the differential optical absorption spectroscopy (DOAS) technique to
 129 IAPCAS/SIF algorithm for TanSat measurement (Frankenberg, 2014b; Sun et al., 2018).

130 The TOA spectral radiance (L_{TOA}^λ) at wavelength λ can be represented as follows:

$$131 \quad L_{TOA}^\lambda = I_t^\lambda \cdot \mu_0 \cdot \left(\rho_0^\lambda + \frac{\rho_s^\lambda \cdot T_\downarrow^\lambda \cdot T_\uparrow^\lambda}{\pi} \right) + F_{TOA}^\lambda \quad (1)$$

132 where I_t^λ is the incident solar irradiance at the TOA, μ_0 is the cosine of the solar zenith angle (SZA), ρ_0^λ is atmospheric path
 133 reflectance, ρ_s^λ is surface reflectance, and T_\downarrow^λ and T_\uparrow^λ are the total atmospheric transmittances along the light-path in the
 134 downstream and upstream directions, respectively. F_{TOA}^λ is the SIF radiance at TOA.

135 The first term on the right of Eq. (1) represents the transmission process of solar radiance. In the micro-windows used in SIF
 136 retrieval, gas absorption is very weak and smooth, and hence, the atmosphere term $\mu_0 \cdot \left(\rho_0^\lambda + \frac{\rho_s^\lambda \cdot T_\downarrow^\lambda \cdot T_\uparrow^\lambda}{\pi} \right)$ can be simplified to a
 137 low-order polynomial that varies with λ (Joiner et al., 2013; Sun et al., 2018); this is always valid as long as the spectrum
 138 fitting range is out of sharp atmospheric absorptions. In the retrieval, the spectral radiance measurement was converted to
 139 logarithmic space by the instrument and the radiative transfer process $f(F_s^{rel}, \mathbf{a})$ was represented as follows:

$$140 \quad f(F_s^{rel}, \mathbf{a}) = \log(\langle I_t + F_s^{rel} \rangle) + \sum_{i=0}^n a_i \cdot \lambda^i \quad (2)$$

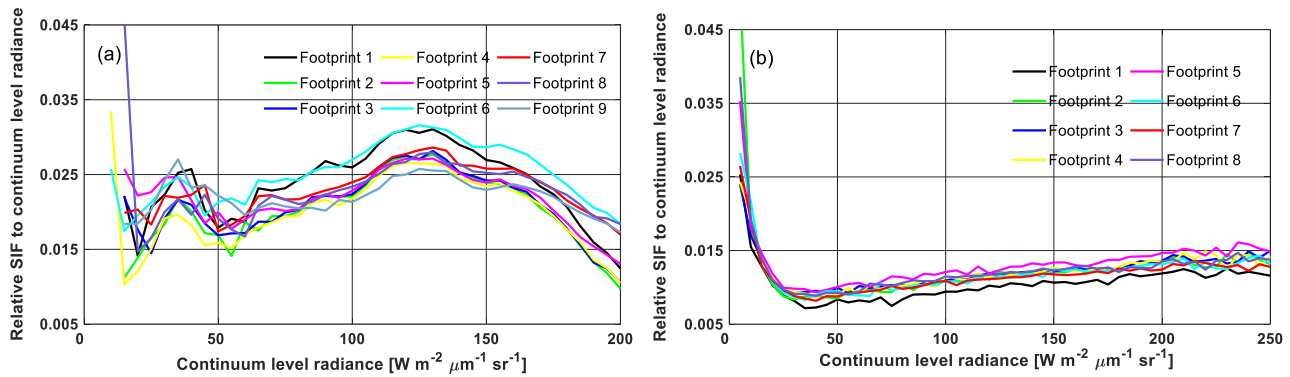

141 where $\langle \rangle$ denote the convolution with the ISRF from line-by-line spectra. The polynomial coefficient \mathbf{a} determines the
 142 wavelength dependence polynomial for the atmosphere term; in the retrieval, we used a second-order polynomial ($n = 2$).
 143 The radiance is normalized to the continuum level; hence, I_t is a normalized disk-integrated solar transmission model, and
 144 F_s^{rel} is the normalized relative SIF. In the micro-window, SIF was regarded as a constant signal due to its small changes.
 145 Although the atmospheric gas absorption was very weak in the micro-window, the weak absorption and the far-wing effects
 146 (O₂ lines) can still change spectral features, which induces errors in spectrum fitting. In other physical-based retrievals, the
 147 surface pressure data of the European Centre for Medium-Range Weather Forecasts (ECMWF) is usually used as the true
 148 surface pressure to simulate the molecular absorption cross-section. However, there is still a difference between the true
 149 surface pressure and the model surface pressure, so we introduced a factor here to reduce the influent of the inaccurate
 150 surface pressure. In IAPCAS/SIF algorithm, we used the ECMWF interim surface pressure ($0.75^\circ \times 0.75^\circ$) to estimate O₂
 151 absorption firstly and then modified the absorption feature by a scale factor. The scale factor is obtained simultaneously in
 152 SIF retrieval to reduce the error induced by the uncertainty in surface pressure. As described by Yang (2020), there is also a
 153 continuum feature in TanSat L1B data that needs to be considered for the high-quality fitting of the O₂-A band. However, in
 154 this study, this continuum feature was not corrected, as the impact of such a smooth continuum variation in the micro-
 155 window is weak and the polynomial continuum model is capable of compensating for most of this effect.

156 The state vector list in the retrieval includes the relative SIF signal F_s^{rel} , a wavenumber shift, the scale of O₂ column
157 absorption for surface pressure correction, and coefficients of the polynomial. The continuum level radiance I_{cont} within the
158 fitting window is calculated using the radiance outside the absorption features in the micro-window and is then used for the
159 actual SIF signal calculation thus: $F = F_s^{rel} \cdot I_{cont}$.
160 In the IAPCAS/SIF algorithm, we used an OEM for state vector optimization in the retrieval process. Unlike XCO₂ retrieval,
161 SIF retrieval employs a state vector with fewer elements and a much simpler forward model, so there is no need to perform
162 complex radiation transmission calculations. Considering the low complexity of SIF retrieval, the Gauss-Newton method
163 was applied in inversion iteratively to find the optimal solution.

164 **2.2 Bias Corrections**

165 A systematic error remains in the raw SIF retrieval output if no bias correction is performed; similar results have been
166 reported in GOSAT and OCO-2 SIF retrieval studies (Frankenberg et al., 2011a, 2011b; Sun et al., 2018). This is because the
167 SIF signal is weak (e.g., typically ~1-2% of the continuum level radiance), which means that even a small issue in the
168 measurement, such as a zero-offset caused by radiometric calibration error, could induce significant bias. Unfortunately, the
169 lack of knowledge on in-flight instrument performance makes it difficult to perform a direct systematic bias correction in the
170 measured spectrum. In the retrieval, a continuum level radiance bin fit was used to estimate the bias. The bins have a
171 continuum level radiance interval of $5 \text{ W m}^{-2} \mu\text{m}^{-1} \text{ sr}^{-1}$. In each bin, the mean bias was estimated using all non-fluorescence
172 measurements, and a piecewise linear function was built from the mean bias of each continuum level radiance interval.
173 The non-fluorescence soundings that were used in the bias estimation were based on the dataset “sounding_landCover” in
174 TanSat L1B data. This dataset depends on the MODIS land cover product and provides a scheme consisting of 17 land cover
175 classifications defined by the International Geosphere-Biosphere Programme. These retrieved measurements marked as
176 “snow and ice,” “barren,” and “sparsely vegetated” were chosen to estimate the bias. Calibrations compensated for most of
177 the instrument degradations, but this alone was not perfect. To reduce the impact from the remaining minor discrepancies,
178 we built the bias correction function daily to obtain bias for each sounding via interpolation of the continuum level radiance
179 (Sun et al., 2017b, 2018).

180 The bias curves shown in Figure 2 differ significantly between TanSat and OCO-2. This is mostly due to the differences in
181 instrument performance and radiometric calibration. In general, the TanSat bias curves exhibited two peaks at radiance levels
182 of approximately 40 and 125 $\text{W m}^{-2} \mu\text{m}^{-1} \text{ sr}^{-1}$, separately, and most biases were larger than 0.015. For OCO-2, the curves
183 dropped sharply at low radiance levels, reaching the valley at a radiance level of approximately 40 $\text{W m}^{-2} \mu\text{m}^{-1} \text{ sr}^{-1}$, and then
184 increased slowly with the radiance level.

185

 187 **Carbon Observatory-2 (OCO-2) on June 16, 2017. The different colors in the legend present different footprints of the satellite**
 188 **frame.**

189 2.3 Data Quality Controls

190 Only data that passed quality control were used in further applications. There were two data quality control processes for the
 191 SIF products: pre-screening and post-screening. Pre-screening focused mainly on cloud screening; only cloud-free
 192 measurements were used in SIF retrieval. A surface pressure difference (SPD), defined as:

$$193 \Delta P_0 = |P_{retrieval} - P_{ECMWF}| \quad (3)$$

194 was used to evaluate cloud contamination along with a chi-square test

$$195 \chi^2 = \sum \frac{(y_{sim} - y_{obs})^2}{y_{noise}^2} \quad (4)$$

196 where y_{sim} , y_{obs} , and y_{noise} represent the model fitting spectrum, observation spectrum, and spectrum noise, respectively.
 197 $P_{retrieval}$ is the apparent surface pressure obtained from O₂-A band surface pressure retrieval, assuming a single scattering
 198 atmosphere. P_{ECMWF} is the ECMWF interim ($0.75^\circ \times 0.75^\circ$) surface pressure. A “cloud-free” measurement was required to
 199 simultaneously satisfy an SPD of less than 20 hPa and a χ^2 value of less than 80. Here, post-screening was applied to filter
 200 out “bad” retrievals; this screening process involved the following steps: (1) SIF retrievals with reduced χ^2 (χ_{red}^2) values
 201 ranging from 0.7 to 1.3 were considered “good” fitting, (2) continuum level radiance outside the range of $15 \sim 200 \text{ W m}^{-2}$
 202 $\mu\text{m}^{-1} \text{ sr}^{-1}$ was screened out to avoid scenes too bright or too dark, and (3) soundings with the SZA higher than 60° were also
 203 filtered out.

204 2.4 IAPCAS versus IMAP-DOAS OCO-2 SIF Retrieval

205 Before applied to TanSat retrievals, we tested the IAPCAS/SIF algorithm on the OCO-2 L1B data first
 206 (OCO2_L1B_Science.8r) and then compared the retrieval results with the OCO-2 L2 Lite SIF product (OCO2_Level
 207 2_Lite_SIF.8r) retrieved by the Iterative Maximum A Posteriori-Differential Optical Absorption Spectroscopy (IMAP-
 208 DOAS) algorithm (Frankenberg, 2014b). The Lite product provides the SIF value for each sounding on a daily basis and
 209 hence the SIF comparison could be performed on the sounding scale for each month.

210 Table 1 displays the relationship of OCO-2 SIF values between the IAPCAS/SIF and IMAP-DOAS at 757 nm micro-
 211 window for each month. Overall, the two SIF products were in good agreement. The linear fitting of the two SIF products
 212 suggests that they are highly correlated, as indicated by the strong linear relationship with R^2 mostly larger than 0.85 and the
 213 root mean square error (RMSE) of about $0.2 \text{ W m}^{-2} \mu\text{m}^{-1} \text{ sr}^{-1}$. Good consistency between the two SIF products implies the
 214 reliability of the IAPCAS/SIF algorithm; thus, it was further applied to TanSat SIF retrieval. However, there was still a small
 215 bias in the comparisons, which was due, most likely, to the impact of differences in the bias correction method, retrieval
 216 algorithm, and fitting window.

217 **Table 1:** Summary of the relationship between the Institute of Atmospheric Physics Carbon Dioxide Retrieval Algorithm for
 218 Satellite Remote Sensing (IAPCAS) OCO-2 and Iterative Maximum A Posteriori-Differential Optical Absorption Spectroscopy
 219 (IMAP-DOAS) OCO-2 solar-induced chlorophyll fluorescence (SIF) products at 757nm micro-window.

month	Number of soundings	Slope	Intercept	R^2	RMSE/ $\text{W m}^{-2} \mu\text{m}^{-1} \text{ sr}^{-1}$
2017/03	1097277	0.85	0.034	0.86	0.18
2017/04	1119464	0.86	0.045	0.87	0.19
2017/05	1054235	0.88	0.041	0.88	0.19
2017/06	1014848	0.91	0.032	0.90	0.19
2017/07	965309	0.92	0.011	0.91	0.19
2017/09	211219	0.88	0.005	0.81	0.23
2017/10	473359	0.88	0.031	0.88	0.17
2017/11	579009	0.87	0.022	0.85	0.19
2017/12	645134	0.87	0.020	0.88	0.16
2018/01	788655	0.87	0.019	0.88	0.17
2018/02*	629995	0.86	0.024	0.87	0.18

220 * Due to the lack of OCO-2 measurements in August 2017, the comparison is only performed for 11 months.

221 3 Results and Discussion

222 3.1 Comparison between TanSat and OCO-2 SIF Measurements

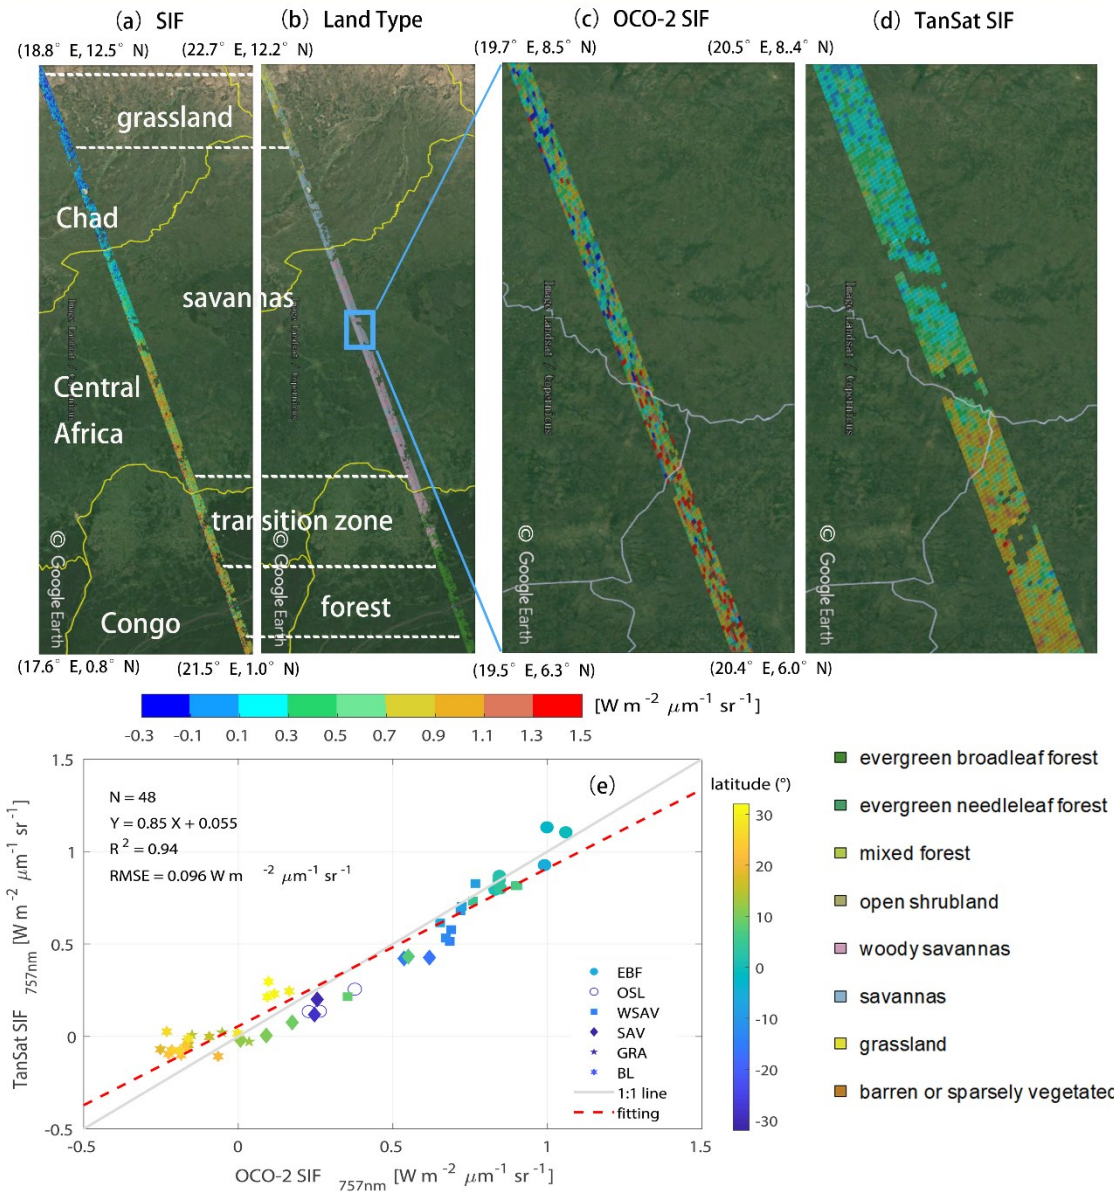

223 The comparison between TanSat and OCO-2 SIF Measurements is a useful and powerful method for further verification of
 224 the IAPCAS/SIF algorithm. The reason for adopting OCO-2 data is that OCO-2 and TanSat have similar observation modes,
 225 including scanning method, transit time, spatial resolution, spectral resolution, and spectral range. The similarities mean that
 226 the SIF product from the two satellite missions can be directly compared. Directly comparing OCO-2 and TanSat SIF
 227 measurements could provide information on joint data application at the sounding scale for further studies. However, an
 228 identical sounding overlap barely exists because the two satellites often have different nadir tracks on the ground, which is
 229 induced by the different temporal and spatial intervals of the two satellite missions. Fortunately, the ground tracks of the two
 230 satellites were relatively close from April 17 to April 23, 2017. A couple of overlapping orbits were found in the
 231 measurements obtained from Africa with the orbit number of 1733 from TanSat and 14890a from OCO-2 (Figure 3). In the

232 comparison, the OCO2_Level 2_Lite_SIF.8r product was used to present the SIF emission over the study area. These
233 overlapping measurements encompassed multiple land cover types, in which the SIF varied within an acceptable time
234 difference (<5 min).

235 Overall, measurements from the two satellites indicated SIF variation with land cover type. The SIF emission over evergreen
236 broadleaf forests was larger than that over savannas, and grasslands exhibited the lowest SIF emission in April (Figure 3a,b).
237 The mean SIF emission over evergreen broadleaf forests was approximately $0.9-1.1 \text{ W m}^{-2} \mu\text{m}^{-1} \text{ sr}^{-1}$, whereas those over
238 savannas and grasslands were $0.5-0.7 \text{ W m}^{-2} \mu\text{m}^{-1} \text{ sr}^{-1}$ and less than $0.1 \text{ W m}^{-2} \mu\text{m}^{-1} \text{ sr}^{-1}$, respectively (Figure 3c,d).
239 Furthermore, we also found a significant difference in the SIF emission intensity over tropical savannas, which was observed
240 by both satellites (Figure 3c,d).

241

242

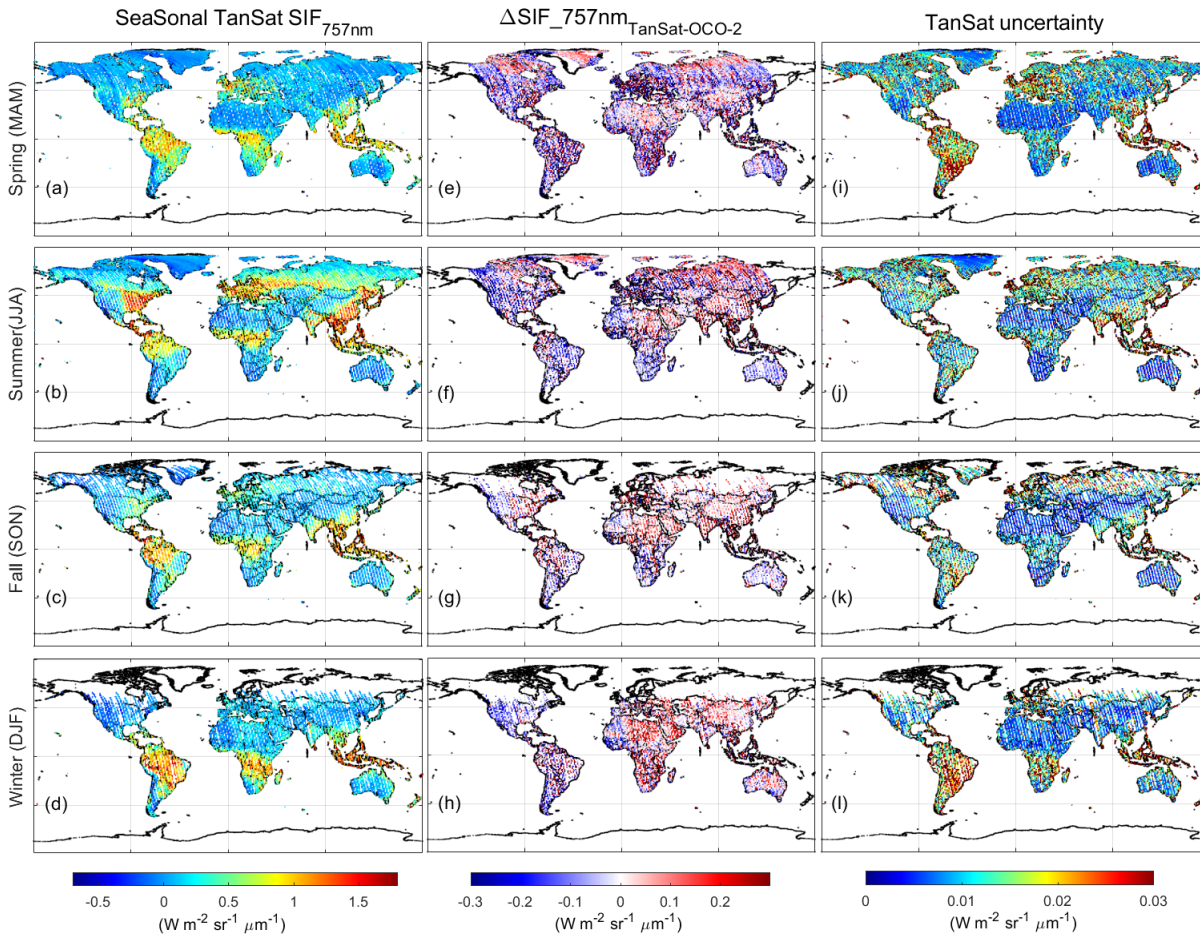

243

244 **Figure 3: Overlapping orbits of TanSat and OCO-2 on April 19, 2017 over Africa displayed in Google Earth, (a) the SIF**
 245 **measurements from both the two satellites and (b) the footprint land cover type were compared. Compared to OCO-2, TanSat has**
 246 **a wider swath width. A zoom-in view over savannas shows variations in the SIF signal measured by (c) OCO-2 and (d) TanSat.**
 247 **The land surface image shown in Google earth is provided by Landsat/Copernicus team. Following the International Geosphere-**
 248 **Biosphere Programme classification scheme, the vertical legend on the bottom right corner depicts the land cover type that occurs**
 249 **in the study area. The middle horizontal color bar represents the intensity of the SIF radiance. (e) Small-area SIF comparison**
 250 **between OCO-2 and TanSat; each data point represents the mean SIF of a degree in latitude (colors) along the track. The marker**
 251 **legend that is shown on the bottom right of the plot indicates the dominant land cover (defined as the majority land cover type of**
 252 **each sounding) in each small area. There are six land cover types including evergreen broadleaf forest (EBF), open shrubland**
 253 **(OSL), woody savanna (WSAV), savanna (SAV), grassland (GRA), and barren land (BL). The red dashed line represents the**
 254 **linear fit between the two SIF products with statistics shown in the upper left of the plot. The gray line indicates a 1:1 relationship**
 255 **for reference.**

256

257 Because the footprint sizes of the two satellites are different, it is difficult to make a direct footprint-to-footprint comparison.
258 Therefore, we made the comparison between the two satellite measurements based on a small area average. Each small area
259 spans a degree in latitude and continues along the track. The small area-averaged SIF comparison is shown in Figure 3e. The
260 results indicate good agreement, with an R^2 of 0.94 and an RMSE of $0.096 \text{ W m}^{-2} \mu\text{m}^{-1} \text{ sr}^{-1}$. Additional ground-based SIF
261 measurement setups (Guanter et al., 2007; Liu et al., 2019; van der Tol et al., 2016; Yang et al., 2015a; Yu et al., 2019)
262 should allow for direct evaluation of satellite retrieval accuracy in the future.

263

264

265 **Figure 4: Global TanSat SIF (left, a-d), differences between TanSat and IAPCAS OCO-2 SIF values (middle, e-h), and the grid-**
266 **cell retrieval uncertainty estimated from TanSat (right, i-l) at $1^\circ \times 1^\circ$ spatial resolution. The maps in each row represent a**
267 **Northern Hemisphere season, i.e., spring (MAM), summer (JJA), fall (SON), and winter (DJF).**

268

269 Figure 4 shows the global SIF comparison between IAPCAS/SIF retrieved OCO-2 and TanSat; this comparison is only
 270 performed at $1^\circ \times 1^\circ$ spatial resolution. In general, the difference in SIF globally is mostly less than $0.3 \text{ W m}^{-2} \mu\text{m}^{-1} \text{ sr}^{-1}$ for
 271 all seasons, and on average, the smallest difference appears in fall. There are regional biases observed in North Africa, South
 272 Africa, South America, and Europe in all seasons except fall. This is mainly caused by the differences in instrument
 273 performance between TanSat and OCO-2, such as the Instrument Respond Function and the Signal-to-Noise. The instrument
 274 performance difference is represented by the different structural characteristics of the bias curves. The bias correction
 275 compensates for most of the bias caused by instrument performance; however, small biases could remain. Furthermore, the
 276 hundreds of kilometers of distance between the OCO-2 and TanSat footprints, for example, over different vegetation regions,
 277 will also cause some measurement discrepancies. The global distribution of the two satellites was also compared with the
 278 official OCO-2 SIF data on the global scale, the results show that the difference between the retrieved SIF maps and the
 279 official map is less than $0.2 \text{ W m}^{-2} \mu\text{m}^{-1} \text{ sr}^{-1}$, indicating that the retrieved SIF data from OCO-2 and TanSat both have good
 280 SIF characterization capabilities on a global scale. The uncertainty σ of each sounding was estimated to validate SIF
 281 reliability and is provided in the product. σ is derived from the retrieval error covariance matrix, $S_e = (K^T S_0^{-1} K)^{-1}$, where K
 282 is the Jacobian matrix from the forward model fitting and S_0 is the measurement error covariance matrix that is calculated
 283 from the instrument spectrum noise. In general, σ ranges from 0.1 to $0.6 \text{ W m}^{-2} \mu\text{m}^{-1} \text{ sr}^{-1}$ for both TanSat and OCO-2
 284 measurements in the 757 nm fitting window, which is of a similar magnitude and data range as those of previous studies (Du
 285 et al., 2018; Frankenberg et al., 2014a). Meanwhile, the standard error of the mean SIF in each grid σ_{meas} was estimated to
 286 represent the gridded retrieval error and natural variability, which is calculated from TanSat SIF values with $\sigma_{meas} = \frac{\sigma_{std}}{\sqrt{n}}$
 287 and $\sigma_{std} = \sqrt{\frac{\sum_{i=1}^n (SIF_i - \overline{SIF})^2}{n}}$, where σ_{std} represents the standard deviation of the grid cell with n soundings, SIF_i is the
 288 retrieved SIF values of each sounding, and \overline{SIF} is the mean SIF value for all measurements in the grid. As depicted in the
 289 right column of Figure 4, the σ_{meas} of each grid cell is much lower than the precision of a single sounding. The σ_{meas} for
 290 South America is larger than that for any other region on the globe (Figure 4i-1). This is similar to that of OCO-2 SIF
 291 retrieval and caused by fewer effective measurements due to the South Atlantic Anomaly (Sun et al., 2018). The difference
 292 in SIF emission values between the two satellites indicates that the collaborative usage of two satellite SIF products still
 293 requires analysis of the impact of instrument differences, although the two satellite SIF products share the same
 294 spatiotemporal pattern on a global scale.

295 3.2 SIF Global Distribution and Temporal Variation

296 The SIF emission intensity reflects the growth status of vegetation due to its correlation with photosynthetic efficiency;
 297 hence, the overall global vegetation status can be represented by global SIF maps for each season. TanSat SIF over a whole
 298 year's cycle, from March 2017 to February 2018, is represented seasonally as a $1^\circ \times 1^\circ$ grid spatially. The seasonal variation

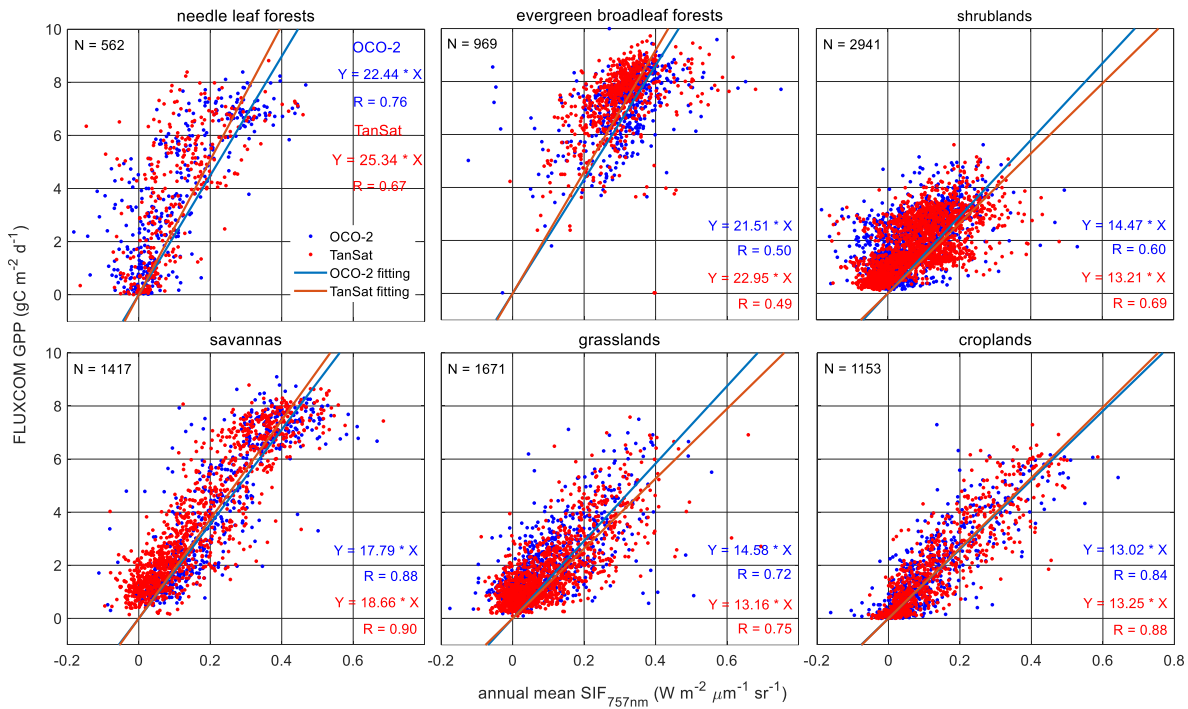

299 in SIF emission is clear in the Northern Hemisphere, i.e., it is enhanced from spring to summer and then decreases (Sun et al.,
300 2018).

301 In general, the SIF emission varied with latitude and the vegetation-covered areas near the equator maintained a continuous
302 SIF emission throughout the year. Large SIF emissions in the Northern Hemisphere, above $1.5 \text{ W m}^{-2} \mu\text{m}^{-1} \text{ sr}^{-1}$, mostly from
303 the eastern U.S., southeast of China, and southern Asia in summer, were due to the large areas of cropland. There was also
304 an obvious SIF emission of $1\text{-}1.2 \text{ W m}^{-2} \mu\text{m}^{-1} \text{ sr}^{-1}$ observed over Central Europe and northeastern China during the summer.
305 In these regions, croplands and deciduous forests contribute to SIF emissions. In the Southern Hemisphere, the strongest SIF
306 emission occurred in the Amazon, with a level of approximately $1\text{-}2 \text{ W m}^{-2} \mu\text{m}^{-1} \text{ sr}^{-1}$ in DJF (Northern Hemisphere winter),
307 where there is an evergreen broadleaf rainforest. Africa, which is covered by evergreen broadleaf rainforests and woody
308 savannas, had an average SIF value of $0.7\text{-}1.5 \text{ W m}^{-2} \mu\text{m}^{-1} \text{ sr}^{-1}$ during the year.

309 The SIF-GPP relationship over different vegetation types was also investigated by comparing the annual mean satellite SIF
310 measurements with the FLUXCOM GPP (Jung et al., 2020; Tramontana et al., 2016) dataset in a $1^\circ \times 1^\circ$ grid over the globe.
311 The FLUXCOM GPP dataset used in the study comprises monthly global gridded flux products with remote sensing and
312 meteorological/climate forcing (RS+METEO) setups, which are derived from mean seasonal cycles according to MODIS
313 data and daily meteorological information (Jung et al., 2020; Tramontana et al., 2016). In the correlation analysis, the high
314 spatial resolution ($0.5^\circ \times 0.5^\circ$) of the FLUXCOM GPP was first resampled to $1^\circ \times 1^\circ$ to keep the same temporal-spatial scale
315 of SIF and GPP data. The satellite-measured SIF is an instantaneous emission signal that varies with incident solar radiance
316 within the day. To reduce the differences caused by the observation time and SZA at different latitudes, we applied a daily
317 adjustment factor to convert the instantaneous SIF emission into a daily mean SIF (Du et al., 2018; Frankenberg et al., 2011b;
318 Sun et al., 2018). The daily adjustment factor d is calculated as follows:

$$319 \quad d = \frac{\int_{t=t_0-12h}^{t=t_0+12h} \cos(SZA(t)) \cdot dt}{\cos(SZA(t_0))} \quad (5)$$

320 where t_0 is the observation time in fractional days and $SZA(t)$ is a function of latitude, longitude, and time for calculating
321 the SZA of the measurements. The annual averaged SIF is calculated from the daily mean SIF. To evaluate the relationship
322 between SIF and GPP on the periodic scale of vegetation growth status, annually-averaged data were used in the regression
323 fitting analysis.

324

325 **Figure 5: Relationship between annual mean SIF and FLUXCOM gross primary production (GPP) from March 2017 to February**
 326 **2018. Blue and red dots represent OCO-2 and TanSat SIF grids, respectively. Fitted lines and statistics for OCO-2 and TanSat are**
 327 **shown in each plot.**

328 Figure 5 shows the linear fits for six vegetation types, including needle leaf forest, evergreen broadleaf forest, shrubland,
 329 savanna, grassland, and cropland. Recent studies have shown a strong linear correlation between SIF and GPP. The TanSat
 330 SIF and the OCO-2 official SIF data were used to estimate the SIF-GPP correlation. To make a direct comparison of the
 331 relationship between SIF and GPP among various vegetation types, we used non-offset linear fitting to indicate the
 332 correlation between satellite SIF and FLUXCOM GPP. For savanna and cropland, there were strong relationships between
 333 the mean SIF and GPP with an R-value above 0.84. The fitting results show that the SIF products of the two satellites have
 334 similar capabilities in characterizing GPP, especially for the evergreen broadleaf forest, savanna, and cropland, with slopes
 335 of approximately 21, 18, and 13, respectively. For shrubland and grassland, the slope of OCO-2 SIF with GPP is higher than
 336 that of TanSat and has a worse correlation. For forests, OCO-2 SIF presents a better correlation with GPP, especially in the
 337 needle leaf forest. As a whole, for the same vegetation type, the SIF-GPP correlations for the two satellites are rather similar,
 338 indicating that the two satellite SIF products have similar capabilities in characterizing GPP. It shows the strong feasibility of
 339 the comprehensive application of different satellite SIF products. For different vegetation types, the SIF-GPP correlations
 340 were significantly different, indicating the different ability of SIF to characterize GPP of different vegetation. It represents
 341 that vegetation type is a key factor in determining the SIF-GPP relationship. The markedly different fitting slopes across
 342 various biomes suggest that the application of SIF in GPP estimation needs more detailed analysis although the evidence of
 343 the strong linear relationship between them.

344 **4 Conclusions**

345 In this paper, we introduced the retrieval algorithm IAPCAS/SIF and its application in TanSat and OCO-2 measurements.
346 One-year (March 2017-February 2018) TanSat SIF data was introduced and compared with OCO-2 measurements in this
347 study. The TanSat and OCO-2 SIF products based on the IAPCAS/SIF algorithm are available on the Cooperation on the
348 Analysis of carbon SATellites data (CASA) website, www.chinageoss.org/tansat. Comparisons between TanSat and OCO-2
349 measurements directly, using a case study, and indirectly, with global $1^{\circ}\times 1^{\circ}$ grid data, showed consistency between the two
350 satellite missions, indicating that the coordinated usage of the two data products is possible in future studies. The correlation
351 analysis between SIF and GPP further verified the feasibility of the comprehensive application of SIF products from
352 different satellite missions. Meanwhile, it should be noticed that the difference in the ability of satellite SIF products to
353 characterize different vegetation types in data applications. With increasing satellites becoming available for SIF
354 observations, space-based SIF observations have recently expanded in range to provide broad spatiotemporal coverage. The
355 next-generation Chinese carbon monitoring satellite (TanSat-2) is now in the preliminary design phase, which is designed to
356 be a constellation of six satellites to measure different kinds of greenhouse gases and trace gases in a more efficient way,
357 including CO₂, CH₄, CO, NO_x, as well as SIF. SIF measurements from TanSat-2 will provide global data products over
358 broader coverage areas with less noise. The improvement in the spatiotemporal resolution of SIF data will benefit GPP
359 predictions based on the numerous studies of the linear relationship between SIF and GPP. In future work, the measurement
360 accuracy should be validated directly using ground-based measurements to ensure data quality.

361 **Data availability**

362 The SIF products of TanSat and OCO-2 by IAPCAS/SIF algorithm are available on the Cooperation on the Analysis of
363 carbon SATellites data (CASA) website (www.chinageoss.org/tansat).

364

365 **Author contributions**

366 L.Y. and D.Y. developed the retrieval algorithm, designed the study, and wrote the paper. Y.L. led the SIF data process and
367 analysis. Y.L., D.Y., Z.C., and J.W. contributed to manuscript organization and revision. C.L. and Y.Z. provided information
368 on the TanSat instrument performance. L.T. provided TanSat in-flight information. M.W. and S.W. provided information on
369 the scientific requirement for data further application. N.L. and D.L. led the TanSat data application. Z.Y. led the TanSat in-
370 flight operation.

371 **Competing interests**

372 The authors declare that they have no conflict of interest.

373 **Acknowledgments**

374 The TanSat L1B data service was provided by the International Reanalysis Cooperation on Carbon Satellites Data (IRCSD)
375 and the Cooperation on the Analysis of carbon SATellites data (CASA). The authors thank OCO-2 Team for providing
376 Level-1B data and Level-2 SIF data products. The authors thank the FLUXCOM team for providing global GPP data. The
377 authors thank Google for allowing free use of Google Earth and reproduction of maps for publication. The authors also thank
378 the Landsat/Copernicus team for providing land surface images for Google Earth.

379 **Financial support**

380 This work has been supported by the Key Research Program of the Chinese Academy of Sciences (ZDRW-ZS-2019-1), and
381 the Youth Program of the National Natural Science Foundation of China (41905029).
