10	Abstract
11	Atmospheric aerosols are an important element of Earth's climate system, and have significant
12	impacts on the environment and on human health. Global aerosol modeling has been
13	increasingly used for operational forecasting and as support to decision making. For example,
14	aerosol analyses and forecasts are routinely used to provide air quality information and alerts in
15	both civilian and military applications. The growing demand for operational aerosol forecasting
16	calls for additional observational data that can be assimilated into models to improve model
17	accuracy and predictive skill. These factors have motivated the development, testing, and
18	release of a new near real-time (NRT) level 2 (L2) aerosol product from the Multi-angle Imaging
19	SpectroRadiometer (MISR) instrument on NASA's Terra platform. The NRT product capitalizes
20	on the unique attributes of the MISR aerosol retrieval approach and product contents, such as
21	reliable aerosol optical depth as well as aerosol microphysical information. Several
22	modifications are described that allow for rapid product generation within a three-hour window
23	following acquisition of the satellite observations. Implications for the product quality and
24	consistency are discussed as compared to the current operational L2 MISR aerosol product.
25	Several ways of implementing additional use-specific retrieval screenings are also highlighted.

### 29 1. Introduction

30

31 Atmospheric aerosols have for long been recognized to influence the climate, environment, and 32 human health (e.g., IPCC, 2013; Lelieveld et al., 2015; Shindell et al., 2013; Turnock et al., 33 2020). They also affect satellite remote sensing of important geophysical parameters such as 34 ocean color (e.g., Frouin et al., 2019; Gordon, 1997) or greenhouse gas abundance (Butz et al., 35 2009; Frankenberg et al., 2012; Houweling et al., 2005). Aerosol particles and their properties 36 have been extensively studied in-situ and remotely: from the ground, in the air, and from space. 37 These observational data vary in spatial and temporal coverage, but usually only offer 38 snapshots of local conditions. Since atmospheric aerosols have a life cycle ranging from hours 39 to days, numerical modeling of their emission, transport, and deposition has filled the coverage 40 gaps and extended our understanding of their global impacts. This has given rise to a number of 41 global aerosol reanalyses (Buchard et al., 2017; Gelaro et al., 2017; Inness et al., 2013, 2019; 42 Lynch et al., 2016; Randles et al., 2017; Rienecker et al., 2011) that provide a long-range, 43 gridded, and internally consistent outlook on aerosol burdens around the world. Furthermore, 44 global aerosol modeling has been increasingly used for operational forecasting (e.g., Xian et al., 45 2019) and as support to decision making, for example in air quality alerts and in non-civilian 46 applications (Liu et al., 2007).

47 The growing demand for consistent gridded aerosol products has been driving 48 development and steady improvement of numerical predictions. For example, the International 49 Cooperation for Aerosol Prediction initiative was founded in 2010 (Benedetti et al., 2011; Reid et 50 al., 2011), with one of its goals being the development of global multi-model aerosol forecasting 51 ensemble for basic research and operational use (Xian et al., 2019). Still, models suffer from 52 often poorly resolved aerosol emissions and sinks and can be affected by errors in the 53 underlying meteorology. As a result, systematic and sampling-related biases in aerosol fields 54 are often found between model simulations and satellite observations (e.g., Buchard et al., 55 2015; Colarco et al., 2010; Lamarque et al., 2013; Zhang and Reid, 2009). An effective way to 56 mitigate some of these problems is by assimilating aerosol observations into numerical models 57 (e.g., Bocquet et al., 2015; Fu et al., 2017; Sekiyama et al., 2010; Di Tomaso et al., 2017; 58 Werner et al., 2019; Zhang et al., 2008). Satellite observations of aerosol optical and 59 microphysical properties are inseparable from these data assimilation activities as they offer the 60 necessary data volume, near-global coverage, and frequent repeat cycle. However, an often-61 considerable latency for generating science-quality "standard" satellite products (8 to 40 hours) 62 renders them unsuitable for operational forecasting. This has led to the development of aerosol

- products within the time frame required by modeling centers, usually three hours from satellite
   overpass. A number of near real-time (NRT) products has emerged.
- 65 One example of a platform that provides users with NRT satellite products and imagery

66 is NASA's Land, Atmosphere Near real-time Capability for EOS (LANCE) project

- 67 (https://earthdata.nasa.gov/earth-observation-data/near-real-time). A range of instruments
- 68 deliver various Level 1 (L1) and Level 2 (L2) data products
- 69 (https://earthdata.nasa.gov/collaborate/open-data-services-and-software/data-information-
- 70 policy/data-levels), including radiances, land surface properties, and atmospheric
- thermodynamics and composition within three hours from satellite observation. NRT aerosol
- 72 products are currently available from the Moderate Resolution Imaging Spectroradiometer
- 73 (MODIS), Ozone Monitoring Instrument (OMI), and Visible Infrared Imaging Radiometer Suite
- 74 (VIIRS). NASA's Multi-angle Imaging SpectroRadiometer (MISR) currently provides NRT
- radiance and cloud motion vector products. The purpose of this paper is to introduce a new
- 76 MISR NRT L2 aerosol product available within LANCE.
- This paper is organized as follows. Section 2 and 3 provide brief descriptions of the MISR instrument and the data processing sequence, respectively. Section 4 first outlines the cloud identification methods employed in the MISR aerosol algorithm and then describes algorithmic modifications introduced in the NRT processing. Adjustments to cloud and retrieval screening parameters and their implications are discussed. The global distributions of the NRT product and comparisons of total and fractional AODs with the standard aerosol product are presented in Section 5. Section 6 provides a summary.
- 84

# 85 2. MISR instrument and aerosol data product

86

87 The MISR instrument flies aboard the NASA Earth Observing System (EOS) Terra satellite, 88 launched in December 1999 to a sun-synchronous descending polar orbit, at an orbital altitude 89 of 705 km, an orbital period of 99 minutes, and an equatorial crossing time of 10:30 a.m. local 90 time. MISR makes 14.56 orbits per day with a repetition cycle (revisit) of 16 days. The orbit 91 tracks are georeferenced to a fixed set of 233 ground paths. With a cross-track swath of about 92 380 km, total Earth coverage is obtained every 9 days at the equator and every 2 days at high 93 latitudes. MISR contains nine pushbroom cameras with viewing angles at the Earth's surface 94

95 ranging from 0° (nadir) to +/- 70.5° oriented along the direction of the flight track. A point on the
96 ground is imaged by all nine cameras in approximately 7 minutes. The cameras make

97 observations of reflected solar radiance in four spectral bands, centered at 446 (blue), 558

98 (green), 672 (red), and 866 (near-infrared) nm. The spatial resolution depends on the camera

99 and wavelength. The red band has a full 275 m resolution in all cameras. The other three

100 spectral channels are averaged onboard to a 1.1 km resolution in global-mode operation (Diner

101 et al., 1998), with the exception of the nadir camera which preserves the full 275 m resolution in

102 all spectral channels. See <u>https://misr.jpl.nasa.gov/Mission/</u> for more details.

MISR employs two processing pathways for aerosol retrievals, one for observations over land (Martonchik et al., 2009), and another for dark water (DW) (Kalashnikova et al., 2013), which applies over deep oceans, seas, and lakes. Previous versions of the MISR aerosol product were extensively validated over the years (e.g., Kahn et al., 2010; Kahn and Gaitley, 2015; Kalashnikova et al., 2013; Shi et al., 2014; Witek et al., 2013) showing high retrieval quality over land and ocean.

109 The current operational version of the MISR aerosol product, designated as version 23 110 (V23), was released publicly in June 2018. It introduced multiple algorithmic, data product, and 111 data usability improvements (Garay et al., 2020; Witek et al., 2018a, 2018b). V23 provides 112 aerosol information with a spatial resolution of 4.4 km x 4.4 km packaged in NetCDF-4 format. 113 Initial validation efforts showed that V23 retrievals are more accurate than previous versions, 114 with most pronounced improvements in the DW algorithm (Garay et al., 2020). V23 retrievals 115 over oceans were extensively validated by Witek et al. (2019), indicating excellent agreement 116 with ground-based observations. Other V23 Aerosol Optical Depth (AOD) evaluation efforts 117 show similar results (e.g., Choi et al., 2019; Sayer et al., 2020; Si et al., 2020; Sogacheva et al., 118 2020). A first regional insight into retrieved particle properties from the MISR V23 aerosol 119 product shows that MISR generally captures the distinct spatial and temporal features of aerosol 120 type in East Asia (Tao et al., 2020). Furthermore, V23 has greatly improved the quality of 121 reported AOD uncertainties, which now realistically represent retrieval errors (Sayer et al., 2020; 122 Witek et al., 2019). This is especially relevant as pixel-level retrieval uncertainties are very 123 important for satellite data assimilation, which is being increasingly used in aerosol modeling 124 studies (Lynch et al., 2016; Shi et al., 2011, 2013; Zhang and Reid, 2010). MISR data and 125 related documentation can be obtained from: https://asdc.larc.nasa.gov/project/MISR. 126 127 3. NRT latency and data description

128

129 MISR currently provides several L1 and L2 near real-time (NRT) radiance and cloud motion

130 vector products (<u>https://earthdata.nasa.gov/earth-observation-data/near-real-time/download-nrt-</u>

131 <u>data/misr-nrt</u>). All MISR NRT processing is based on Level 0 data downlinked in observational

132 sessions. These session-based files, representing portions of a single MISR orbit, usually cover

133 between 10 to 50 minutes of observations, as compared to the full orbit period of 98.9 minutes.

134 This session-based processing is necessary to allow for the fast product delivery required for

135 NRT applications.

136The new NRT L2 aerosol product file content, described in Data Product Specification137(<u>https://asdc.larc.nasa.gov/documents/misr/DPS\_AEROSOL\_NRT\_V023.20210430.pdf</u>), is138equivalent to the standard aerosol product (Garay et al., 2020). The NRT L2 aerosol product file139name convention is:

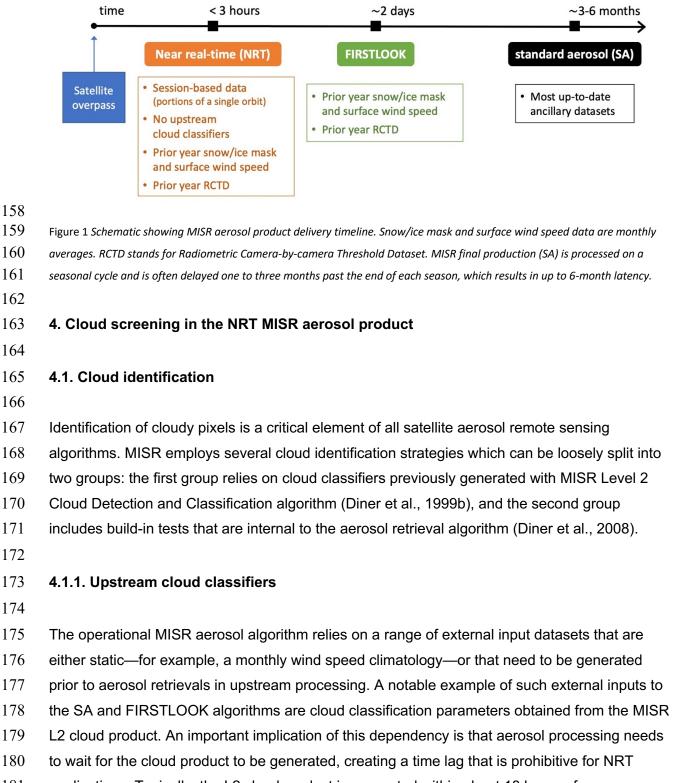

140 MISR AM1 AS AEROSOL T{yyyymmddHHMMSS} P{ppp} O{oooooo} F13 0023.nc, where 141 'yyyy', 'mm', and 'dd' are the year, month, and day, and 'HH', 'MM' and 'SS' are the hour, 142 minute, and seconds, respectively. Furthermore, {ppp} is the three-digit path identifier (between 143 001 and 233) and {oooooo} is the six-digit orbit number. The NRT L2 aerosol product files are 144 available for download within three hours of acquisition at NASA's Atmospheric Science Data 145 Center (ASDC) (https://asdc.larc.nasa.gov/project/MISR). 146 For clarity, it is important to distinguish between the three different MISR L2 aerosol 147 products: NRT, FIRSTLOOK, and standard aerosol (SA) product (see Figure 1). NRT is 148 generated within a three-hour time interval after acquisition and uses the same ancillary inputs 149 as FIRSTLOOK. These include the monthly gridded (1.0 degree) snow/ice mask and surface 150 wind speed from the Terrestrial Atmospheric and Surface Climatology (TASC) database and the 151 seasonal Radiometric Camera-by-camera Threshold Dataset (RCTD) (Diner et al., 1999a). Both 152 NRT and FIRSTLOOK utilize TASC and RCTD datasets from the current month/season in the 153 prior year. The FIRSTLOOK product is generated within two days from acquisition and includes 154 cloud classification parameters obtained from the L1 and L2 cloud products. The SA product is

available after final processing is performed on a seasonal basis and within three months past

156 the end of the season, which results in a 3–6-month latency. The final processing utilizes the

157 most recent snow/ice and wind speed data.

### MISR aerosol product production sequence

applications. Typically, the L2 cloud product is generated within about 18 hours of overpass,

and the MISR L2 FIRSTLOOK aerosol processing is completed within about 2 days. In order to
 produce an L2 aerosol product within an about three-hour time frame, the algorithm needs to
 operate without the upstream cloud classifiers.

185 Two specific L2 cloud classification parameters utilized in FIRSTLOOK and SA aerosol 186 processing are the MISR Stereoscopically-Derived Cloud Mask (SDCM) and the Angular 187 Signature Cloud Mask (ASCM) (Diner et al., 1999b; Girolamo and Davies, 1994). In addition to 188 these L2 products, the Radiometric Camera-by-camera Cloud Mask (RCCM) (Diner et al., 189 1999a; Girolamo and Davies, 1995) retrieved in L1B processing is also employed. All three 190 parameters are reported at 1.1 km x 1.1 km resolution. It should be noted that RCCM also 191 serves as an input to the algorithm that generates SDCM and ASCM, indicating that these 192 parameters are not independent.

193 In the FIRSTLOOK and SA algorithm, the RCCM, SDCM, and ASCM cloud masks are 194 used together to determine whether a particular 1.1 km x 1.1 km subregion is clear or cloudy. 195 The implication is that if any of the 9 MISR cameras is designated as cloudy in a subregion, this 196 subregion is excluded from aerosol retrieval. The clear/cloudy decision logic depends on the 197 underlying surface type, assigned into three categories: land, water, and snow/ice. Generally, a 198 "clear" outcome is favored over the two most frequently used surface types, land and water, 199 assigning a subregion as cloudy only if the RCCM and SDCM masks indicate a cloud. The logic 200 is considerably more conservative over snow/ice surfaces due to difficulties in distinguishing 201 clouds from the underlying bright features. Details of the cloud mask decision logic over different 202 surface types can be found in Diner et al. (2008).

Analyzing three months of V23 L2 SA product (March, April, May, 2020) indicates that the cloud masks along with the brightness test (see 4.1.2) lead to screening of about 50% of retrievals. As such, they have the largest impact on identifying and removing pixels where clouds might be present. These masks and decision pathways, however, have their deficiencies and additional checks were put in place to further decrease the frequency of cloudcontaminated aerosol retrievals.

209

### 210 **4.1.2.** Built-in cloud detection methods

211

212 In addition to the cloud masks retrieved in the L1B processing (RCCM) and from the L2 Cloud

213 Detection and Classification algorithm (SDCM, ASCM), the MISR aerosol retrieval algorithm

relies on three internal tests to further identify cloudy pixels that might have escaped earlier

detection. These are (1) the *brightness test*, (2) the *angle-to-angle smoothness test*, and (3) the

angle-to-angle correlation test. Details of these tests can be found in Diner et al. (2008) or Witek
et al. (2013), but a short summary is provided here for completeness.

The brightness test is employed to identify clouds that lacked sufficient texture to be picked up by SDCM. For each surface type a fixed threshold is adopted on measured bidirectional reflectance factors (BRFs), and when exceeded in all spectral bands for at least one camera, it renders a subregion unsuitable for aerosol retrieval. The thresholds are set to 1.0, 0.5, and 0.5 for snow/ice, land, and water surfaces, respectively. The value of 1.0 means that the brightness test is effectively turned off over snow/ice. Furthermore, the brightness test does not override subregions that were identified as clear by RCCM.

The angular smoothness test checks for unusually large variations in the measured equivalent reflectances as a function of camera angle, the premise being that in the absence of artifacts or subpixel clouds, the measured radiance should change smoothly from camera to camera. The test is achieved by fitting a polynomial to equivalent reflectances, separately for aft (+nadir) and forward (+nadir) cameras and each spectral band, and checking if the goodness of fit metric (definition in Diner et al., 2008) exceeds a threshold. If in at least one case the test fails, the subregion is eliminated.

232 Finally, the angle-to-angle correlation test also investigates radiance smoothness and 233 correlation between camera angles, which makes it conceptually similar to the angular 234 smoothness test, but instead utilizes high-resolution information form the red spectral band. It 235 uses 4 x 4 arrays of the 275m spatial resolution red band equivalent reflectances in each 1.1 km 236 x 1.1 km subregion. The test then evaluates spatial variability within the 4 x 4 array for each 237 camera and compares it to a variability within a camera-average template. Variances, 238 covariances, and normalized cross-correlations are calculated (see Diner et al., (2008) for 239 details). If the variability within a camera deviates considerably from the average, this camera 240 might have sub-pixel clouds or other contaminants, and as a result the subregion is excluded 241 from aerosol retrievals.

242 In the three months of data analyzed in this study (March, April, May 2020), the relative 243 occurrence of retrieval screening due the above-mentioned internal tests are about 4.0% and 244 0.1% for the correlation and smoothness tests, respectively. These statistics come from 245 analyzing the output field Aerosol Retrieval Screening Flags and as such they do not 246 represent the absolute rates of success of each individual test. That is because the tests are 247 performed in a sequential order and if one of them fails, tests that are next in sequence are not 248 performed. For SA product generation, the order is: upstream cloud mask described in 4.1.1, 249 the brightness test, the correlation test, and the smoothness test. For example, the correlation

- test is only performed on pixels that already passed the upstream cloud tests as well as the
- brightness test. Additionally, the brightness test does not have its own flag in the
- Aerosol\_Retrieval\_Screening\_Flags output but is grouped together with the upstream cloud classifiers.
- 254

## **4.2. Retrieval screening using regional cloud parameters**

256

257 Methods described in section 4.1 focus on identifying and excluding cloudy 1.1 km x 1.1 km 258 subregions from the aerosol retrieval process. The retrieval region consists of 16  $(4 \times 4)$ 259 subregions. These methods are highly effective at removing cloud-contaminated pixels, but 260 since they rely on MISR visible wavelengths they might miss certain cloud signatures more 261 easily detected in the infrared spectrum (e.g., Gao et al., 1993). For example, MODIS routinely 262 uses its reflective and emissive infrared channels to detect optically thin cirrus clouds 263 (Ackerman et al., 2010; Levy et al., 2013). As a result, MISR cloud detection methods 264 occasionally fail, which leads to visible outliers in retrieved AODs (Witek et al., 2018b). For that 265 reason, an additional set of screenings is applied in an effort to eliminate such unusually high 266 AOD retrievals (Garay et al., 2020). Two of these additional methods look at overall cloudiness 267 in the retrieval region (consisting of 4 x 4 subregions) as well as in a larger area consisting of 3 268 x 3 regions (12 x 12 subregions). The Cloud Screening Parameter (CSP) represents the fraction 269 of clear grid cells within a region, whereas Cloud Screening Parameter Neighbor 3x3 (CSP9) is 270 similar to CSP but for the larger area. If CSP is below 0.7 and CSP9 below 0.5, the retrieval is 271 not reported in the final product intended for most users. However, it is still included in the 272 product's AUXILIARY subcategory and annotated with the term "Raw" to indicate that the 273 product has not undergone recommended quality screenings. 274

- **4.3. Adjusting cloud screening thresholds**
- 276

### **4.3.1. Performance of the prototype NRT product**

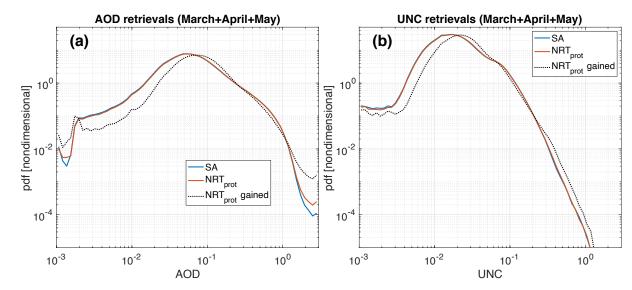

278

279 This subsection presents results and analysis of prototype NRT aerosol retrievals. These are

280 obtained prior to any threshold and screening adjustments included in the final version of the

- 281 product. To differentiate between the final and the prototype NRT products, the latter is donated
- as NRTprot.

283 As mentioned in the previous section, the NRT processing cannot rely on the cloud 284 masks generated in the L1 and L2 cloud products, namely the RCCM, SDCM, and ASCM. This 285 implies that potentially less screening of cloudy subregions would be applied, increasing the 286 probability of cloud contamination in aerosol retrievals. However, some of the burden of cloud 287 identification is picked up by the built-in cloud tests described in section 4.1.2. The frequency of 288 these tests identifying cloudy pixels increases in NRT processing in comparison to standard 289 processing, in large part mitigating the negative consequences resulting from the lack of the 290 upstream cloud masks. This is well evidenced by examining the normalized probability density 291 functions (pdfs) of AOD from spring 2020 (Figure 2). The SA (red) and NRTprot (blue) lines are 292 very similar, indicating that the built-in cloud tests substitute to a significant extent for the 293 missing upstream cloud masks in generating the NRTprot product. The largest difference occurs 294 in the high-AOD range, suggesting that NRTprot has more retrievals in this regime. The black 295 dotted line shows a *pdf* of the NRT<sub>prot</sub> AOD retrievals that do not have a matching SA retrieval. 296 This is labeled as "NRT<sub>prot</sub> gained" as it represents additional retrievals obtained in NRT 297 processing due to the lack of external cloud masks. The "NRT<sub>prot</sub> gained" pdf is clearly shifted 298 towards higher AODs, confirming that the NRTprot processing tends to retrieve higher AODs in 299 places where SA is not available.

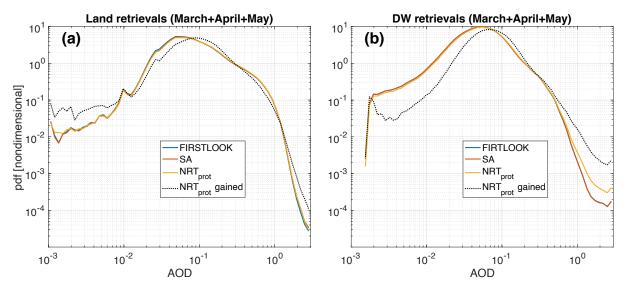

300

Figure 2 (a) AOD normalized probability density functions from SA, prototype NRT, and prototype NRT retrievals that do not
 have a matching SA equivalent (labeled as NRT<sub>prot</sub> gained); (b) same as in (a) but for retrieved AOD uncertainties (UNC). Data
 statistics for AODs are provided in Table 1.

Figure 3 shows *pdf*s of AOD but with retrievals separated between DW (Fig. 3a) and land (Fig. 3b). These *pdf*s indicate that the retrievals over oceans are the main source of

306 increased frequency of high-AODs in the NRT<sub>prot</sub> product. The *pdf*s over land are virtually 307 unchanged, including a slightly flattened but still relatively comparable distribution of the "NRT<sub>prot</sub> 308 gained" retrievals (Fig. 3b). The additional statistics of the data presented in Figs. 2 and 3, 309 including the retrieval count, the mean AOD, and the geometric mean AOD, which is better 310 suited for log-normal distributions of AOD (Sayer and Knobelspiesse, 2019), are provided in 311 Table 1. Note that the number of NRT<sub>prot</sub> gained is not the same as the number of NRT<sub>prot</sub> minus 312 SA. This is because some SA retrievals do not have their NRTprot equivalent, making the SA 313 count larger than it would have been otherwise.

In the 3-month period analyzed in this study (March, April, May, 2020), the NRT<sub>prot</sub> processing leads to about 6.4% more retrievals than SA (see Table 1). 5.5 million NRT<sub>prot</sub> retrievals do not have a matching SA retrieval (NRT gained), and the majority of them (67%) are DW retrievals. The overall geometric means are almost identical in SA and NRT<sub>prot</sub>, although small variations in this statistic are seen in DW and land categories. The NRT gained have visibly higher mean and geometric mean values, the increase coming mainly from DW retrievals. These basic statistics warrant a further look at the NRT<sub>prot</sub> performance over DW.

322 Figure 3 AOD pdfs for land (a) and DW (b) retrievals, respectively. Data statistics are provided in Table 1.

	Α	ll retrieva	ls	DW			Land		
	SA	NRT <sub>prot</sub>	NRT <sub>prot</sub> gained	SA	NRT <sub>prot</sub>	NRT <sub>prot</sub> gained	SA	NRT <sub>prot</sub>	NRT <sub>prot</sub> gained
<i>N</i> (×10 <sup>6</sup> )	49.7	52.9	5.5	27.6	30.7	3.7	22.1	22.2	1.8

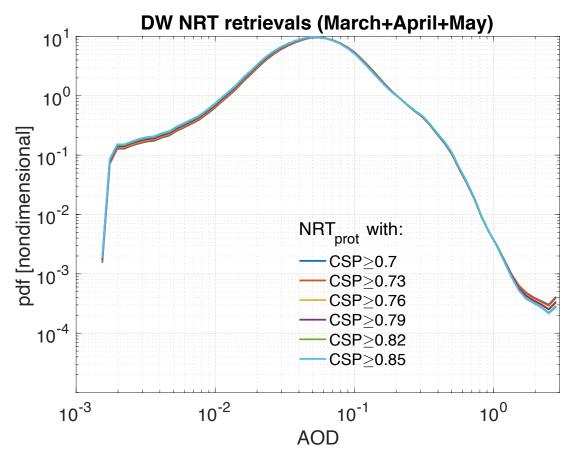

mean	0.168	0.169	0.171	0.111	0.115	0.146	0.240	0.243	0.224
geomean	0.111	0.112	0.122	0.083	0.085	0.106	0.160	0.162	0.161

- Table 1 Additional statistics for the data presented in Figs. 2 and 3 (statistic for FIRSTLOOK not shown). NRT gained stands for the prototype NRT retrievals that do not have a matching SA equivalent; geomean stands for the geometric mean AOD.
- 325

## 326 **4.3.2.** Sensitivity to CSP and CSP9 thresholds in DW retrievals

327

328 One way to screen potentially cloud-contaminated high-AOD retrievals is to adjust thresholds on 329 CSP and CSP9 parameters (Garay et al., 2020). This is furthermore justified by the fact that in 330 the absence of RCCM, SDCM, and ASCM in NRTprot processing, fewer cloudy subregions are 331 identified in a retrieval area and consequently CSP and CSP9 have by default lower values. 332 This argument provides strong justification for investigating sensitivity to increased CSP and 333 CSP9 thresholds in the NRTprot processing. 334 The SA product uses the thresholds of CSP=0.7 and CSP9=0.5 (Garay et al., 2020); 335 when the values of CSP and CSP9 are below these thresholds in a retrieval region, the aerosol 336 retrieval is removed from the data field recommended for users. Figure 4 and Table 2 show pdfs 337 and AOD statistics for different thresholds of CSP and CSP9 parameters in the NRTprot product 338 over dark water surfaces. There are only minor changes in the pdfs when the thresholds are 339 increased, including in the high-AOD regime. The mean and geometric mean decrease 340 gradually but slowly; even at the highest considered thresholds (0.85 for CSP and 0.75 for 341 CSP9) these statistics are still above the SA values. At the same time the number of passing 342 NRT<sub>prot</sub> retrievals decreases considerably faster, with almost 19% of retrievals lost when the 343 highest thresholds are used. These results indicate that adjusting CSP and CSP9 thresholds is 344 not an effective strategy to constraining NRTprot retrievals.

346 Figure 4 Prototype NRT AOD pdfs over dark water surfaces from spring 2020 obtained with different CSP and CSP9 cloud-

347	screening thresholds. Data statistics are provided in Table 2.

screening AOD retrievals. The arithmetic mean values are accompanied by their respective  $\pm$  one standard deviations.

## **4.3.3. Sensitivity to ARCI threshold in DW retrievals**

353 V23 of the MISR aerosol product introduced a new parameter, called the aerosol retrieval 354 confidence index (ARCI), that is used to screen high-AOD retrieval outliers caused by cloud 355 contamination and other factors (Witek et al., 2018b). ARCI, defined only for DW retrievals, 356 proved to be an efficient metric at filtering out potentially cloud-contaminated AOD retrievals. In 357 standard processing, retrievals with ARCI < 0.15 are removed from the recommended user 358 field, but are retained in the AUXILIARY group. The 0.15 threshold is well supported through 359 statistical analysis (Witek et al., 2018b), although some erroneous AODs still pass this 360 screening method, suggesting that increasing this threshold might be beneficial in NRT 361 processing.

Figure 5 and Table 3 show pdfs and AOD statistics for different thresholds of ARCI in the 362 363 NRT<sub>prot</sub> product. In this case the differences between ARCI thresholds are quite noticeable, 364 especially in the high-AOD range of retrievals. Increasing the ARCI threshold to 0.2 leads to a 365 loss of about 11% of NRTprot DW retrievals, but the resulting mean and geometric mean are 366 lower than the SA values. At the same time, the absolute number of NRTprot DW retrievals (27.4 367 million) is still comparable to the number of SA DW retrievals (27.6 million). The pdfs and the 368 statistics suggest that increasing the NRTprot ARCI threshold from 0.15 to 0.18 leads to a 369 product that has similar characteristics to SA.

371 Figure 5 Prototype NRT AOD pdfs from spring 2020 obtained with different ARCI thresholds. Data statistic are provided in Table

372 з.

370

N (×10 <sup>6</sup> )	30.7	30.0	29.4	28.7	28.0	27.4	SA

# 375 **4.3.4. Recommendation for NRT processing**

- 376
- 377 The statistical analyses presented in the previous sections indicate that the lack of RCCM,
- 378 SDCM, and ASCM in NRT processing has negative consequences on the product, especially by

379 allowing more, potentially cloud-contaminated, high-AOD DW retrievals to pass screening 380 criteria. Adjusting build-in cloud screening thresholds on CSP and CSP9 brings only limited 381 benefits at the cost of losing a considerable percentage of retrievals. However, the ARCI 382 threshold adjustments result in much closer statistical correspondence between the NRTprot and 383 standard AOD retrievals. For that reason, a revised ARCI threshold of 0.18 is implemented in 384 NRT processing. Since the unscreened retrievals, as well as the ARCI parameter, are also 385 provided in the AUXILIARY group of the product, users are encouraged to experiment with their 386 own thresholds which might prove more beneficial in specific applications or geographic areas. 387

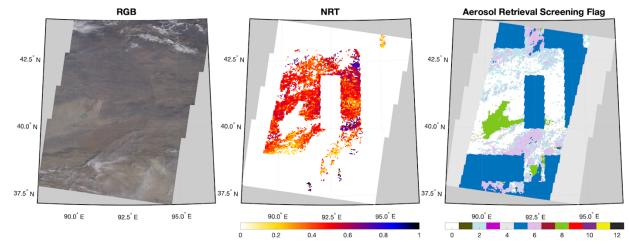

#### 388 4.4. Cloud/clear decision logic over snow/ice

389

390 In section 4.1.1 the impact of upstream cloud classifiers in standard processing—namely the 391 RCCM, SDCM, and ASCM—on the subregion's cloud/clear designation was briefly described. 392 The decision pathway depends on the underlying surface type, which can be either land, water, 393 or snow/ice. Over land and water, the "cloud" outcome is only obtained when both RCCM and 394 SDCM designate the subregion as cloudy. In the absence of RCCM and SDCM the default 395 outcome is "clear". Over snow/ice, however, the logic is more restrictive and favors the "cloudy" 396 designation (Diner et al., 2008). Specifically, when the upstream cloud classifiers are not 397 available, the subregion designation is set to "cloudy" by default. This has important implications 398 on aerosol retrievals in areas where snow and ice occur seasonally.

399 The snow/ice surface mask, unlike land and water, is not static and changes every 400 month. Furthermore, the snow/ice mask input to MISR aerosol processing has a 1.0-degree 401 horizontal resolution, which is re-gridded to a 1.1 km resolution corresponding to the resolution 402 of MISR subregion. In FIRSTLOOK processing, the snow/ice mask from the same month but in 403 the previous year is used. The final SA processing is performed when the current year's monthly 404 snow/ice mask becomes available. The NRT processing, similarly to FIRSTLOOK, relies on the 405 previous year's snow/ice mask. Additionally, given the lack of upstream cloud classifiers, the 406 snow/ice areas are designated as "cloudy" for aerosol retrieval purposes. This is well visualized 407 in Figure 6 which shows the visible image and the corresponding maps of AOD and Aerosol 408 Retrieval Screening Flag in the NRT processing. The dark blue color (index 5) denotes cloudy 409 regions determined using the snow/ice cloud logic. The box-like nature of the excluded areas is 410 associated with the coarse resolution of the snow/ice mask (1.0 degree). The previous year's 411 mask might also not be representative of the current conditions on the ground. It is worth noting 412 that the FIRSTLOOK product often suffers from the same exclusion rules as NRT. This is

- 413 because of the strict clear/cloud logic over snow/ice surfaces which favors the cloudy outcome;
- 414 in the case shown in Fig. 6 the AOD gaps in FIRSTLOOK (not shown) look very similar to the
- 415 NRT product.

417 Figure 6 Example of snow/ice masking in NRT AOD retrievals. (Left) Visible image of the retrieval area. (Center) Corresponding

418 NRT AOD retrievals. (Right) NRT Aerosol Retrieval Screening Flag for the same area; the dark blue color denotes regions

419 *designated as cloudy.* 

Several attempts have been made by the MISR science team to improve NRT aerosol retrievals in snow/ice covered areas. However, identifying and isolating snow-covered surfaces in the absence of upstream cloud classifiers proves very challenging. The quality of aerosol retrievals is often negatively affected in such conditions. For that reason, and in an attempt to eliminate as many NRT AOD outliers as possible, the current snow/ice logic is retained in the NRT aerosol processing.

426

416

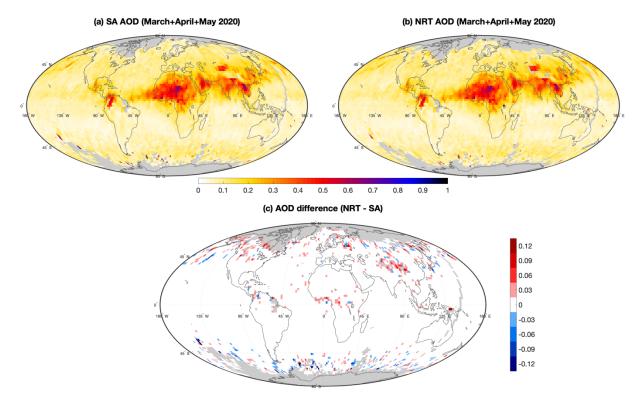

## 427 **5. NRT and SA product comparisons**

428

## 429 **5.1. Total AOD**

- 430
- $431 \qquad \text{In this section, geographic distributions of MISR AOD retrievals from SA and NRT products are}$
- 432 analyzed. The datasets encompass three months, March, April, and May of 2020. The NRT
- 433 retrievals are screened with the revised ARCI threshold of 0.18 as suggested in section 4.3.4.
- 434 The spatial overlap of the SA and NRT data is achieved using an intersect of the X\_Dim and
- 435 Y\_Dim fields in the two data products.

- Figure 7 shows the global distributions of geometric mean AOD from the (a) SA and (b)
  NRT products. The retrievals are gridded at 2-by-2-degree spatial resolution. Fig. 7c shows the
  AOD difference between the two products (NRT SA).
- 439 The largest AOD differences are seen in areas with climatologically high cloud cover, 440 especially over the Southern Ocean, and over land in areas where potential snow cover could 441 be an issue. Over the Southern Ocean the SA AODs are predominantly higher than the NRT 442 AODs. This is due to the increased ARCI threshold in NRT (0.18 vs. 0.15 in SA) which brings in 443 more aggressive screening of cloud-contaminated retrievals (Witek et al., 2018b). Over land, 444 where the ARCI parameter is not available, the gridded NRT AODs tend to be higher than the 445 SA AODs, which is in part related to the differences in snow/ice mask between the two 446 products. Still, the AOD differences in Fig. 7c are rather small and reflect sampling issues rather 447 than any systematic deficiencies in NRT processing. At the same time the lack of cloud 448 classifiers in NRT does not adversely affect AOD distributions, which is consistent with the 449 statistical analysis presented in section 4.2.3.

450

451 Figure 7 (a) Global distribution of SA AOD geometric mean values across March, April, and May of 2020 on a 2-by-2-degree

- 452 spatial resolution; (b) same as in (a) but for NRT AOD; and (c) AOD difference between SA and NRT. Grid points with less than 15
- 453 retrievals are excluded.

## 454 **5.2. Retrieval yields**

Figure 8 complements Fig. 7 by showing (a) the SA retrieval count distribution as well as (b) the retrieval count difference between the SA and NRT products.

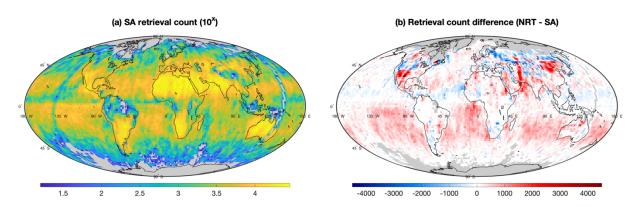

Figure 8 (a) Decimal logarithm of the retrieval count from the SA product in March, April, and May of 2020; (b) retrieval count
 difference between SA and NRT. Presented values are gridded at 2-by-2-degree spatial resolution and grid points with less than
 15 retrievals are excluded.

461 The highest number of retrievals is found over the subtropical continents where the 462 cloud cover is usually the smallest. Over the subtropical oceans in the Southern Hemisphere the 463 NRT retrieval counts are typically higher than in SA, which results from the absence of upstream 464 cloud classifiers in NRT processing and subsequently fewer subregions being excluded as 465 cloudy. Note that this increase in retrieval count caused by the lack of cloud classifiers is not 466 compensated by the increased ARCI threshold in NRT processing (ARCI ≥ 0.18), which always 467 reduces the number of retrievals when compared to the default SA threshold (ARCI≥0.15). The 468 lack of hemispheric symmetry in this case is likely due to the seasonal variability (only months in 469 northern spring are analyzed here). Over land the lack of upstream cloud classifiers also results 470 in higher number of NRT retrievals in certain regions, but the surface type exclusion rules 471 reverse this pattern, especially at higher latitudes. The conservative cloud logic over snow/ice 472 surfaces in NRT processing often results in the lower number of NRT retrievals in the high 473 latitudes of the northern hemisphere. 474

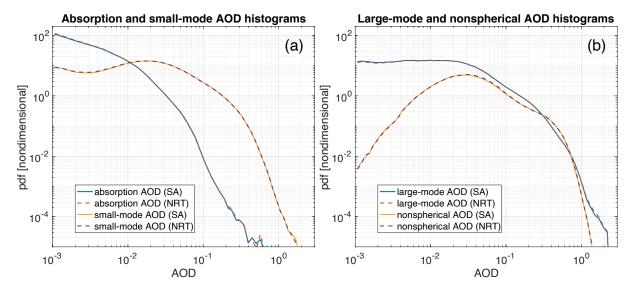

A metric relevant to the potential use of the NRT product in data assimilation is the retrieval yield per model grid point. The retrieval yield can be measured as, for example, the number of 1° x 1° grid cells that have at least 15 valid satellite retrievals in them. From this perspective, the NRT product has a retrieval yield that is about 0.7% higher than the SA product, based on the three months of data analyzed in this study.

479

457

480 **5.3. Fractional AOD** 

482 MISR's multi-angle retrieval approach enables characterization of aerosol optical and 483 microphysical properties, such as fractional AODs associated with particle absorption, 484 nonsphericity, and size (see e.g., Kahn and Gaitley, 2015). This attribute of the MISR SA 485 product has been applied to many climate and air quality studies and inclusion of this capability 486 in the NRT product would benefit data assimilation for numerical prediction of atmospheric 487 aerosols (Benedetti et al., 2018). Consequently, this section provides preliminary statistical 488 comparisons of the SA and NRT absorption AOD along with small-mode, large-mode, and 489 nonspherical AOD. The results shown in Fig. 9 indicate that the probability density functions of 490 these aerosol properties in the NRT product are statistically equivalent to the SA product. This 491 assessment reaffirms the consistency of the NRT and SA products. Future studies will examine 492 geographic and statistical differences and other particle properties in more detail.

493

Figure 9 Normalized probability density functions for select MISR particle property retrievals in March, April, and May 2020.
 Solid lines represent SA retrievals and dashed represent NRT retrievals. (a) absorption AOD and small-mode AOD retrievals; (b)
 large-mode AOD and nonspherical AOD retrievals. The differences between the SA and NRT products are negligible.

497

### 498 **6.** Summary

499

500 The MISR V23 aerosol product, publicly available since mid-2018, is a high-resolution state-of-501 the-art data product from NASA's Terra flagship mission. V23 AOD retrievals have remarkable 502 accuracy compared against ground-based observations (Garay et al., 2020; Tao et al., 2020; 503 Witek et al., 2019) and the product is more intuitive and easier to use than previous versions. 504 The product is available within 2 days from satellite overpass as a FIRSTLOOK version, and 505 within 3-to-6 months as a final science-quality SA version that employs the most up-to-date ancillary datasets. In response to the needs of operational user communities, a new MISR L2
 NRT aerosol product has been developed with a 3-hour latency.

508 The new NRT algorithm does not depend on the upstream cloud classifiers that are 509 generated in L1 and L2 cloud processing. The lack of cloud classifiers is in large part mitigated 510 by the aerosol algorithm's built-in cloud identification methods. Analysis of the prototype NRT 511 product has shown an increased frequency of high-AOD retrievals, especially over oceans and 512 in climatologically cloudy areas, likely due to an increase in cloud contamination. Adjusting the 513 ARCI threshold in DW retrievals proves highly effective at eliminating some of these high-AOD 514 outliers and improves the NRT product's statistical agreement with the SA version. The new 515 NRT aerosol product applies an ARCI threshold of 0.18 to mitigate cloud contamination in the 516 absence of upstream cloud masks in NRT processing. The remaining differences in statistical 517 and geographic distributions between the NRT and SA AODs, which includes information from 518 the L2 cloud product, are small and largely confined to areas with high cloud cover. 519 The results of this study also serve as an example of the effects of screening threshold 520 adjustments in MISR aerosol retrievals on AOD statistics and distributions. Researchers

521 interested in particular applications and/or specific geographic regions are encouraged to

522 experiment with their own threshold to achieve most optimal results. The NRT aerosol product

523 contains both the recommended product contained within the main science directory

524 "4.4\_KM\_PRODUCTS" that has the stricter ARCI threshold (ARCI $\geq$ 0.18), and the unscreened

525 product without the additional cloud and ARCI filtering designed for more experienced users,

526 located within the AUXILIARY group.

527

# 528 Acknowledgements

529 This research was carried out at the Jet Propulsion Laboratory, California Institute of

530 Technology, under a contract with the National Aeronautics and Space Administration. Support

531 from the MISR project is acknowledged. Special thanks to Andrew Sayer, Jeffrey Reid, and one

anonymous reviewer for carefully reading the manuscript and providing valuable comments.

533

# 534 **Data availability**

535 The MISR V23 SA and NRT data is publicly available and can be downloaded from

536 <u>https://l0dup05.larc.nasa.gov/cgi-bin/MISR/main.cgi</u>. MISR NRT data is not stored permanently

and is only available for three to six months from the time of aquisition; please contact the

538 corresponding author to request the NRT data from the months analyzed in this study.
