10 **Abstract**

11 Atmospheric aerosols are an important element of Earth's climate system, and have significant
12 impacts on the environment and on human health. Global aerosol modeling has been
13 increasingly used for operational forecasting and as support to decision making. For example,
14 aerosol analyses and forecasts are routinely used to provide air quality information and alerts in
15 both civilian and military applications. The growing demand for operational aerosol forecasting
16 calls for additional observational data that can be assimilated into models to improve model
17 accuracy and predictive skill. These factors have motivated the development, testing, and
18 release of a new near real-time (NRT) level 2 (L2) aerosol product from the Multi-angle Imaging
19 SpectroRadiometer (MISR) instrument on NASA's Terra platform. The NRT product capitalizes
20 on the unique attributes of the MISR aerosol retrieval approach and product contents, such as
21 reliable aerosol optical depth as well as aerosol microphysical information. Several
22 modifications are described that allow for rapid product generation within a three-hour window
23 following acquisition of the satellite observations. Implications for the product quality and
24 consistency are discussed as compared to the current operational L2 MISR aerosol product.
25 Several ways of implementing additional use-specific retrieval screenings are also highlighted.

29 **1. Introduction**

30

31 Atmospheric aerosols have for long been recognized to influence the climate, environment, and
32 human health (e.g., IPCC, 2013; Lelieveld et al., 2015; Shindell et al., 2013; Turnock et al.,
33 2020). They also affect satellite remote sensing of important geophysical parameters such as
34 ocean color (e.g., Frouin et al., 2019; Gordon, 1997) or greenhouse gas abundance (Butz et al.,
35 2009; Frankenberg et al., 2012; Houweling et al., 2005). Aerosol particles and their properties
36 have been extensively studied in-situ and remotely: from the ground, in the air, and from space.
37 These observational data vary in spatial and temporal coverage, but usually only offer
38 snapshots of local conditions. Since atmospheric aerosols have a life cycle ranging from hours
39 to days, numerical modeling of their emission, transport, and deposition has filled the coverage
40 gaps and extended our understanding of their global impacts. This has given rise to a number of
41 global aerosol reanalyses (Gelaro et al., 2017; Inness et al., 2013, 2019; Lynch et al., 2016;
42 Rienecker et al., 2011) that provide a long-range, gridded, and internally consistent outlook on
43 aerosol burdens around the world. Furthermore, global aerosol modeling has been increasingly
44 used for operational forecasting (e.g., Xian et al., 2019) and as support to decision making, for
45 example in air quality alerts and in non-civilian applications (Liu et al., 2007).

46 The growing demand for consistent gridded aerosol products has been driving
47 development and steady improvement of numerical predictions. Still, models suffer from often
48 poorly resolved aerosol emissions and sinks and can be affected by errors in the underlying
49 meteorology. As a result, systematic and sampling-related biases in aerosol fields are often
50 found between model simulations and satellite observations (e.g., Buchard et al., 2015; Colarco
51 et al., 2010; Lamarque et al., 2013; Zhang and Reid, 2009). An effective way to mitigate some
52 of these problems is by assimilating aerosol observations into numerical models (e.g., Bocquet
53 et al., 2015; Fu et al., 2017; Sekiyama et al., 2010; Di Tomaso et al., 2017; Werner et al., 2019;
54 Zhang et al., 2008). Satellite observations of aerosol optical and microphysical properties are
55 inseparable from these data assimilation activities as they offer the necessary data volume,
56 near-global coverage, and frequent repeat cycle. However, an often-considerable latency for
57 generating science-quality “standard” satellite products (8 to 40 hours) renders them unsuitable
58 for operational forecasting. This has led to the development of aerosol products within the time
59 frame required by modeling centers, usually three hours from satellite overpass. A range of near
60 real-time (NRT) products has emerged.

61 One example of a platform that provides users with NRT satellite products and imagery
62 is NASA's Land, Atmosphere Near real-time Capability for EOS (LANCE) project

63 (<https://earthdata.nasa.gov/earth-observation-data/near-real-time>). A range of instruments
64 deliver various Level 1 (L1) and Level 2 (L2) data products
65 ([https://earthdata.nasa.gov/collaborate/open-data-services-and-software/data-information-](https://earthdata.nasa.gov/collaborate/open-data-services-and-software/data-information-policy/data-levels)
66 [policy/data-levels](https://earthdata.nasa.gov/collaborate/open-data-services-and-software/data-information-policy/data-levels)), including radiances, land surface properties, and atmospheric
67 thermodynamics and composition within three hours from satellite observation. NRT aerosol
68 products are currently available from the Moderate Resolution Imaging Spectroradiometer
69 (MODIS), Ozone Monitoring Instrument (OMI), and Visible Infrared Imaging Radiometer Suite
70 (VIIRS). NASA's Multi-angle Imaging SpectroRadiometer (MISR) currently provides NRT
71 radiance and cloud motion vector products. The purpose of this paper is to introduce a new
72 MISR NRT L2 aerosol product.

73 This paper is organized as follows. Section 2 and 3 provide brief descriptions of the
74 MISR instrument and the data processing sequence, respectively. Section 4 first outlines the
75 cloud identification methods employed in the MISR aerosol algorithm and then describes
76 algorithmic modifications introduced in the NRT processing. Adjustments to cloud and retrieval
77 screening parameters and their implications are discussed. The global distributions of the NRT
78 product are analyzed in Section 5. Section 6 provides a summary.

79

80 **2. MISR instrument and aerosol data product**

81

82 The MISR instrument flies aboard the NASA Earth Observing System (EOS) Terra satellite,
83 launched in December 1999 to a sun-synchronous descending polar orbit, at an orbital altitude
84 of 705 km, an orbital period of 99 minutes, and an equatorial crossing time of 10:30 a.m. local
85 time. MISR makes 14.56 orbits per day with a repetition cycle (revisit) of 16 days. The orbit
86 tracks are georeferenced to a fixed set of 233 ground paths. With a cross-track swath of about
87 380 km, total Earth coverage is obtained every 9 days at the equator and every 2 days at high
88 latitudes.

89 MISR contains nine pushbroom cameras with viewing angles at the Earth's surface
90 ranging from 0° (nadir) to +/- 70.5° oriented along the direction of the flight track. A point on the
91 ground is imaged by all nine cameras in approximately 7 minutes. The cameras make
92 observations of reflected solar radiance in four spectral bands, centered at 446 (blue), 558
93 (green), 672 (red), and 866 (near-infrared) nm. The spatial resolution depends on the camera
94 and wavelength. The red band has a full 275 m resolution in all cameras. The other three
95 spectral channels are averaged onboard to a 1.1 km resolution in global-mode operation (Diner

96 et al., 1998), with the exception of the nadir camera which preserves the full 275 m resolution in
97 all spectral channels. See <https://misr.jpl.nasa.gov/Mission/> for more details.

98 MISR employs two processing pathways for aerosol retrievals, one for observations over
99 land (Martonchik et al., 2009), and another for dark water (DW) (Kalashnikova et al., 2013),
100 which applies over deep oceans, seas, and lakes. Previous versions of the MISR aerosol
101 product were extensively validated over the years (e.g., Kahn et al., 2010; Kahn and Gaitley,
102 2015; Kalashnikova et al., 2013; Shi et al., 2014; Witek et al., 2013) showing high retrieval
103 quality over land and ocean.

104 The current operational version of the MISR aerosol product, designated as version 23
105 (V23), was released publicly in June 2018. It introduced multiple algorithmic, data product, and
106 data usability improvements (Garay et al., 2020; Witek et al., 2018a, 2018b). V23 provides
107 aerosol information with a spatial resolution of 4.4 km x 4.4 km packaged in NetCDF-4 format.
108 Initial validation efforts showed that V23 retrievals are more accurate than previous versions,
109 with most pronounced improvements in the DW algorithm (Garay et al., 2020). V23 retrievals
110 over oceans were extensively validated by Witek et al. (2019), indicating excellent agreement
111 with ground-based observations. Other V23 Aerosol Optical Depth (AOD) evaluation efforts
112 show similar results (e.g., Choi et al., 2019; Sayer et al., 2020; Si et al., 2020; Sogacheva et al.,
113 2020). A first regional insight into retrieved particle properties from the MISR V23 aerosol
114 product shows that MISR generally captures the distinct spatial and temporal features of aerosol
115 type in East Asia (Tao et al., 2020). Furthermore, V23 has greatly improved the quality of
116 reported AOD uncertainties, which now realistically represent retrieval errors (Sayer et al., 2020;
117 Witek et al., 2019). This is especially relevant as pixel-level retrieval uncertainties are very
118 important for satellite data assimilation, which is being increasingly used in aerosol modeling
119 studies (Lynch et al., 2016; Shi et al., 2011, 2013; Zhang and Reid, 2010). MISR data and
120 related documentation can be obtained from: <https://asdc.larc.nasa.gov/project/MISR>.

121

122 **3. NRT latency and data description**

123

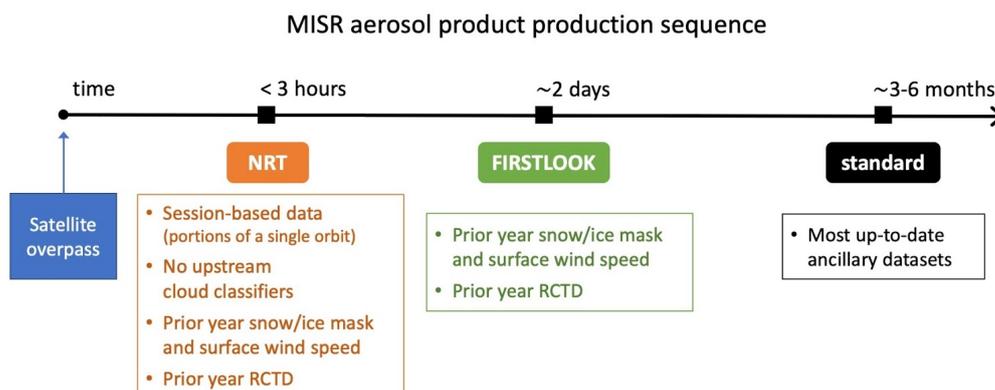

124 MISR currently provides several L1 and L2 near real-time (NRT) radiance and cloud motion
125 vector products ([https://earthdata.nasa.gov/earth-observation-data/near-real-time/download-nrt-
126 data/misr-nrt](https://earthdata.nasa.gov/earth-observation-data/near-real-time/download-nrt-data/misr-nrt)). All MISR NRT processing is based on Level 0 data downlinked in observational
127 sessions. These session-based files, representing portions of a single MISR orbit, usually cover
128 between 10 to 50 minutes of observations, as compared to the full orbit period of 98.9 minutes.

129 This session-based processing is necessary to allow for the fast product delivery required for
130 NRT applications.

131 The new NRT L2 aerosol product file content, described in Data Product Specification
132 (ref), is equivalent to the standard aerosol product (Garay et al., 2020). The NRT L2 aerosol
133 product file name convention is:
134 MISR_AM1_AS_AEROSOL_T{yyyymmddHHMMSS}_P{ppp}_O{ooooo}_F13_0023.nc, where
135 'yyyy', 'mm', and 'dd' are the year, month, and day, and 'HH', 'MM' and 'SS' are the hour,
136 minute, and seconds, respectively. Furthermore, {ppp} is the three-digit path identifier (between
137 001 and 233) and {ooooo} is the six-digit orbit number. The NRT L2 aerosol product files are
138 available for download within three hours of acquisition at NASA's Atmospheric Science Data
139 Center (ASDC) (<https://asdc.larc.nasa.gov/project/MISR>).

140 For clarity, it is important to distinguish between the MISR L2 NRT, FIRSTLOOK, and
141 standard aerosol products (see Figure 1). NRT is generated within a three-hour time interval
142 after acquisition and uses the same ancillary inputs as FIRSTLOOK. These include the monthly
143 gridded (1.0 degree) snow/ice mask and surface wind speed from the Terrestrial Atmospheric
144 and Surface Climatology (TASC) database and the seasonal Radiometric Camera-by-camera
145 Threshold Dataset (RCTD) (Diner et al., 1999a). Both NRT and FIRSTLOOK utilize TASC and
146 RCTD datasets from the current month/season in the prior year. The FIRSTLOOK product is
147 generated within two days from acquisition and includes cloud classification parameters
148 obtained from the L1 and L2 cloud products. The standard aerosol product is available after final
149 processing is performed on a seasonal basis and within three months past the end of the
150 season, which results in a 3–6-month latency. The final processing utilizes the most recent
151 snow/ice and wind speed data.

152

153 Figure 1 Schematic showing MISR aerosol product delivery timeline. Snow/ice mask and surface wind speed data are monthly
154 averages. RCTD stands for Radiometric Camera-by-camera Threshold Dataset. MISR final production (standard product) is
155 processed on a seasonal cycle and is often delayed one to three months past the end of each season, which results in up to 6-
156 month latency.

157

158 4. NRT aerosol product cloud screening

159

160 4.1. Cloud identification

161

162 Identification of cloudy pixels is a critical element of all satellite aerosol remote sensing
163 algorithms. MISR employs several cloud identification strategies which can be loosely split into
164 two groups: The first group relies on cloud classifiers previously generated with MISR Level 2
165 Cloud Detection and Classification algorithm (Diner et al., 1999b), and the second group
166 includes build-in tests that are internal to the aerosol retrieval algorithm (Diner et al., 2008).

167

168 4.1.1. Upstream cloud classifiers

169

170 The operational MISR aerosol algorithm relies on a range of external input datasets that are
171 either static—for example, a monthly wind speed climatology—or that need to be generated
172 prior to aerosol retrievals in upstream processing. A notable example of such external inputs to
173 the standard and FIRSTLOOK algorithms are cloud classification parameters obtained from the
174 MISR L2 cloud product. An important implication of this dependency is that aerosol processing
175 needs to wait for the cloud product to be generated, creating a time lag that is prohibitive for
176 NRT applications. Typically, the L2 cloud product is generated within about 18 hours of

177 overpass, and the MISR L2 FIRSTLOOK aerosol processing is completed within about 2 days.
178 In order to produce an L2 aerosol product within an about three-hour time frame, the algorithm
179 needs to operate without the upstream cloud classifiers.

180 Two specific L2 cloud classification parameters utilized in aerosol processing are the
181 MISR Stereoscopically-Derived Cloud Mask (SDCM) and the Angular Signature Cloud Mask
182 (ASCM) (Diner et al., 1999b; Girolamo and Davies, 1994). In addition to these L2 products, the
183 Radiometric Camera-by-camera Cloud Mask (RCCM) (Diner et al., 1999a; Girolamo and
184 Davies, 1995) retrieved in L1B processing is also employed. All three parameters are reported
185 at 1.1 km x 1.1 km resolution. It should be noted that RCCM also serves as an input to the
186 algorithm that generates SDCM and ASCM, indicating that these parameters are not
187 independent.

188 In the standard aerosol algorithm, the RCCM, SDCM, and ASCM cloud masks are used
189 together to determine whether a particular 1.1 km x 1.1 km subregion is clear or cloudy. The
190 implication is that if any of the 9 MISR cameras is designated as cloudy in a subregion, this
191 subregion is excluded from aerosol retrieval. The clear/cloudy decision logic depends on the
192 underlying surface type, assigned into three categories: land, water, and snow/ice. Generally, a
193 “clear” outcome is favored over the two most frequently used surface types, land and water,
194 assigning a subregion as cloudy only if the RCCM and SDCM masks indicate a cloud. The logic
195 is considerably more conservative over snow/ice surfaces due to difficulties in distinguishing
196 clouds from the underlying bright features. Details of the cloud mask decision logic over different
197 surface types can be found in Diner et al. (2008).

198 Analyzing three months of V23 L2 aerosol product (March, April, May, 2020) indicates
199 that the cloud masks along with the brightness test (see 4.1.2) lead to screening of about 50%
200 of retrievals. As such, they have the largest impact on identifying and removing pixels where
201 clouds might be present. These masks and decision pathways, however, have their deficiencies
202 and additional checks were put in place to further decrease the frequency of cloud-
203 contaminated aerosol retrievals.

204

205 **4.1.2. Build-in cloud detection methods**

206

207 In addition to the cloud masks retrieved in the L1B processing (RCCM) and from the L2 Cloud
208 Detection and Classification algorithm (SDCM, ASCM), the MISR aerosol retrieval algorithm
209 relies on three internal tests to further identify cloudy pixels that might have escaped earlier
210 detection. These are (1) the *brightness test*, (2) the *angle-to-angle smoothness test*, and (3) the

211 *angle-to-angle correlation test*. Details of these tests can be found in Diner et al. (2008) or Witek
212 et al. (2013), but a short summary is provided here for completeness.

213 The brightness test is employed to identify clouds that lacked sufficient texture to be
214 picked up by SDCM. For each surface type a fixed threshold is adopted on measured
215 bidirectional reflectance factors (BRFs), and when exceeded in all spectral bands for at least
216 one camera, it renders a subregion unsuitable for aerosol retrieval. The thresholds are set to
217 1.0, 0.5, and 0.5 for snow/ice, land, and water surfaces, respectively. The value of 1.0 means
218 that the brightness test is effectively turned off over snow/ice. Furthermore, the brightness test
219 does not override subregions that were identified as clear by RCCM.

220 The angular smoothness test checks for unusually large variations in the measured
221 equivalent reflectances as a function of camera angle, the premise being that in the absence of
222 artifacts or subpixel clouds, the measured radiance should change smoothly from camera to
223 camera. The test is achieved by fitting a polynomial to equivalent reflectances, separately for aft
224 (+nadir) and forward (+nadir) cameras and each spectral band, and checking if the goodness of
225 fit metric (definition in Diner et al., 2008) exceeds a threshold. If in at least one case the test
226 fails, the subregion is eliminated.

227 Finally, the angle-to-angle correlation test also investigates radiance smoothness and
228 correlation between camera angles, which makes it conceptually similar to the angular
229 smoothness test, but instead utilizes high-resolution information from the red spectral band. It
230 uses 4 x 4 arrays of the 275m spatial resolution red band equivalent reflectances in each 1.1 km
231 x 1.1 km subregion. The test then evaluates spatial variability within the 4 x 4 array for each
232 camera and compares it to a variability within a camera-average template. Variances,
233 covariances, and normalized cross-correlations are calculated (see Diner et al., (2008) for
234 details). If the variability within a camera deviates considerably from the average, this camera
235 might have sub-pixel clouds or other contaminants, and as a result the subregion is excluded
236 from aerosol retrievals.

237 In the three months of data analyzed in this study (March, April, May 2020), the relative
238 occurrence of retrieval screening due the above-mentioned internal tests are about 4.0% and
239 0.1% for the correlation and smoothness tests, respectively. These statistics come from
240 analyzing the output field *Aerosol_Retrieval_Screening_Flags* and as such they do not
241 represent the absolute rates of success of each individual test. That is because the tests are
242 performed in a sequential order and if one of them fails, tests that are next in sequence are not
243 performed. For standard aerosol product generation, the order is: upstream cloud mask
244 described in 4.1.1, the brightness test, the correlation test, and the smoothness test. For

245 example, the correlation test is only performed on pixels that already passed the upstream cloud
246 tests as well as the brightness test. Additionally, the brightness test does not have its own flag in
247 the *Aerosol_Retrieval_Screening_Flags* output but is grouped together with the upstream cloud
248 classifiers.

249

250 **4.2. Retrieval screening using regional cloud parameters**

251

252 Methods described in section 4.1 focus on identifying and excluding cloudy 1.1 km x 1.1 km
253 subregions from the aerosol retrieval process. The retrieval region consists of 16 (4 x 4)
254 subregions. These methods are highly effective at removing cloud-contaminated pixels, but
255 since they rely on MISR visible wavelengths they might miss certain cloud signatures more
256 easily detected in the infrared spectrum (e.g., Gao et al., 1993). For example, MODIS routinely
257 uses its reflective and emissive infrared channels to detect optically thin cirrus clouds
258 (Ackerman et al., 2010; Levy et al., 2013). As a result, MISR cloud detection methods
259 occasionally fail, which leads to visible outliers in retrieved AODs (Witek et al., 2018b). For that
260 reason, an additional set of screenings is applied in an effort to eliminate such unusually high
261 AOD retrievals (Garay et al., 2020). Two of these additional methods look at overall cloudiness
262 in the retrieval region (consisting of 4 x 4 subregions) as well as in a larger area consisting of 3
263 x 3 regions (12 x 12 subregions). The Cloud Screening Parameter (CSP) represents the fraction
264 of clear grid cells within a region, whereas Cloud Screening Parameter Neighbor 3x3 (CSP9) is
265 similar to CSP but for the larger area. If CSP is below 0.7 and CSP9 below 0.5, the retrieval is
266 not reported in the final product intended for most users. However, it is still included in the
267 product's AUXILIARY subcategory and annotated with the term "Raw" to indicate that the
268 product has not undergone recommended quality screenings.

269

270 **4.3. Adjusting cloud screening thresholds**

271

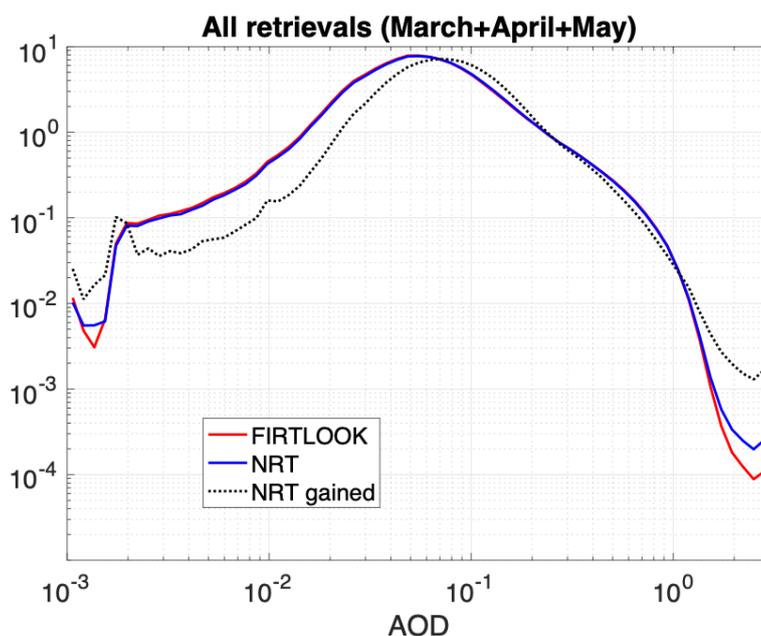

272 **4.3.1. Performance of the prototype NRT product**

273

274 This subsection presents results and analysis of prototype NRT aerosol retrievals. These are
275 obtained prior to any threshold and screening adjustments included in the final version of the
276 product. To differentiate between the final and the prototype NRT products, the latter is denoted
277 as NRT_{prot}.

278 As mentioned in the previous section, the NRT processing cannot rely on the cloud
279 masks generated in the L1 and L2 cloud products, namely the RCCM, SDCM, and ASCM. This
280 implies that potentially less screening of cloudy subregions would be applied, increasing the
281 probability of cloud contamination in aerosol retrievals. However, some of the burden of cloud
282 identification is picked up by the built-in cloud tests described in section 4.1.2. The frequency of
283 these tests identifying cloudy pixels increases in NRT processing in comparison to standard
284 processing, in large part mitigating the negative consequences resulting from the lack of the
285 upstream cloud masks. This is well evidenced by examining the normalized probability density
286 functions (*pdfs*) of AOD from spring 2020 (Figure 2). The FIRSTLOOK (red) and NRT_{prot} (blue)
287 lines are very similar, indicating that the built-in cloud tests substitute to a significant extent for
288 the missing upstream cloud masks in generating the NRT_{prot} product. The largest difference
289 occurs in the high-AOD range, suggesting that NRT_{prot} has more retrievals in this regime. The
290 black dotted line shows a *pdf* of the NRT_{prot} AOD retrievals that do not have a matching
291 FIRSTLOOK retrieval. This is labeled as “NRT gained” as it represents additional retrievals
292 obtained in NRT processing due to the lack of external cloud masks. The “NRT gained” *pdf*
293 is clearly shifted towards higher AODs, confirming that the NRT_{prot} processing tends to retrieve
294 higher AODs in places where FIRSTLOOK is not available.

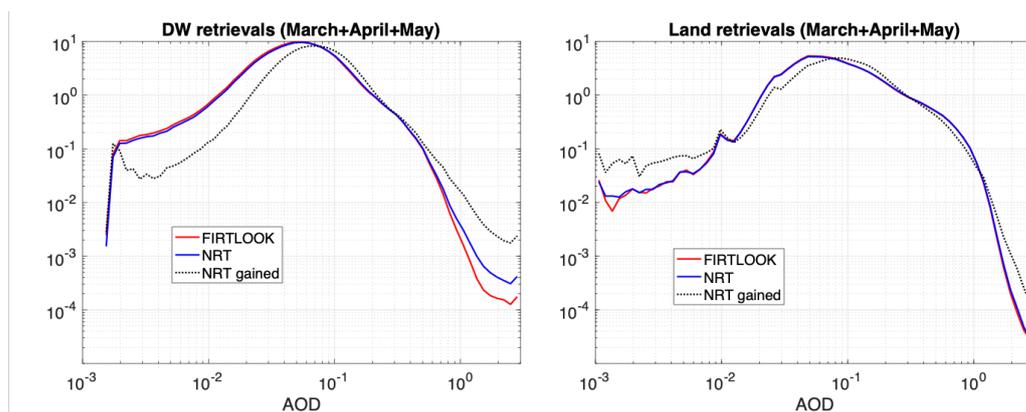

295
296 *Figure 2* AOD normalized probability density functions from FIRSTLOOK, prototype NRT, and prototype NRT retrievals that do not
297 have a matching FIRSTLOOK equivalent (labeled as NRT gained). Data statistics are provided in Table 1.

298 Figure 3 shows *pdfs* of AOD but with retrievals separated between DW (Fig. 3a) and
 299 land (Fig. 3b). These *pdfs* indicate that the retrievals over oceans are the main source of
 300 increased frequency of high-AODs in the NRT_{prot} product. The *pdfs* over land are virtually
 301 unchanged, including a similar distribution of the “NRT gained” retrievals (Fig. 3b). The
 302 additional statistics of the data presented in Figs. 2 and 3, including the retrieval count, the
 303 mean AOD, and the geometric mean AOD, which is better suited for log-normal distributions of
 304 AOD (Sayer et al. 2020), are provided in Table 1.

305 In the 3-month period analyzed in this study (March, April, May, 2020), the NRT_{prot}
 306 processing leads to about 6.5% more retrievals than FIRSTLOOK (see Table 1). 5.4 million
 307 NRT_{prot} retrievals do not have a matching FIRSTLOOK retrieval (NRT gained), and the majority
 308 of them (68%) are DW retrievals. The overall geometric means are almost identical in
 309 FIRSTLOOK and NRT_{prot}, although small variations in this statistic are seen in DW and land
 310 categories. The NRT gained have visibly higher mean and geometric mean values, the increase
 311 coming mainly from DW retrievals. These basic statistics warrant a further look at the NRT_{prot}
 312 performance over DW.

313

314 Figure 3 Same as in Fig. 2 but with retrievals separated between DW (a) and land (b). Data statistics are provided in Table 1.

	All retrievals			DW			Land		
	FL	NRT	NRT gained	FL	NRT	NRT gained	FL	NRT	NRT gained
$N (\times 10^6)$	50.4	53.7	5.4	27.9	31.1	3.7	22.5	22.6	1.7
<i>mean</i>	0.167	0.167	0.172	0.110	0.115	0.146	0.237	0.240	0.228

<i>geomean</i>	0.110	0.111	0.121	0.082	0.085	0.106	0.157	0.159	0.161
----------------	-------	-------	-------	-------	-------	-------	-------	-------	-------

315 *Table 1 Additional statistics for the data presented in Figs. 2 and 3. FL stand for FIRSTLOOK; NRT gained stands for the prototype*
316 *NRT retrievals that do not have a matching FIRSTLOOK equivalent; geomean stands for the geometric mean AOD.*

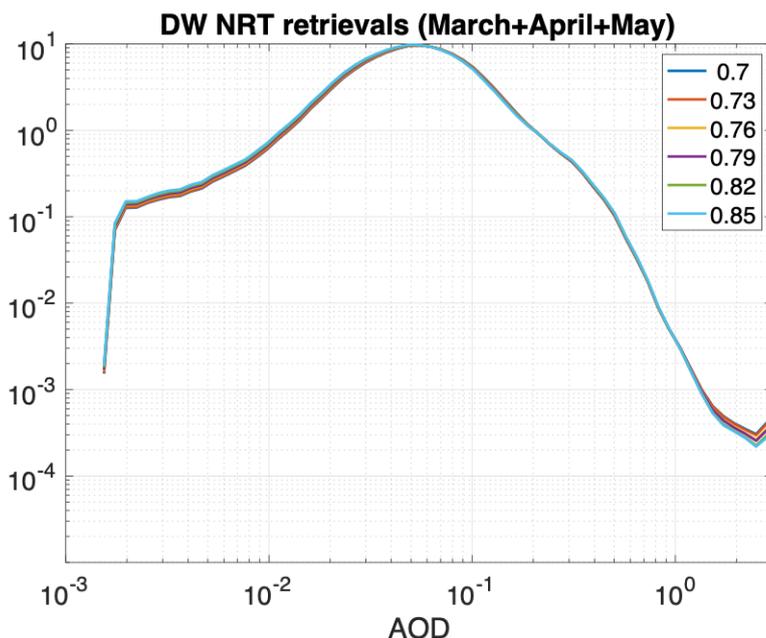

317

318 **4.3.2. Sensitivity to CSP and CSP9 thresholds in DW retrievals**

319

320 One way to screen potentially cloud-contaminated high-AOD retrievals is to adjust thresholds on
321 CSP and CSP9 parameters (Garay et al., 2020). This is furthermore justified by the fact that in
322 the absence of RCCM, SDCM, and ASCM in NRT_{prot} processing, less cloudy subregions are
323 identified in a retrieval area and consequently CSP and CSP9 have by default lower values.
324 This argument provides strong justification for investigating sensitivity to increased CSP and
325 CSP9 thresholds in the NRT_{prot} processing.

326 The standard product uses the thresholds of CSP=0.7 and CSP9=0.5 (Garay et al.,
327 2020); when the values of CSP and CSP9 are below these thresholds in a retrieval region, the
328 aerosol retrieval is removed from the data field recommended for users. Figure 4 and Table 2
329 show *pdfs* and AOD statistics for different thresholds of CSP and CSP9 parameters in the
330 NRT_{prot} product over dark water surfaces. There are only minor changes in the *pdfs* when the
331 thresholds are increased, including in the high-AOD regime. The mean and geometric mean
332 decrease gradually but slowly; even at the highest considered thresholds (0.85 for CSP and
333 0.75 for CSP9) these statistics are still above the FIRSTLOOK values. At the same time the
334 number of passing NRT_{prot} retrievals decreases considerably faster, with over 19% of retrievals
335 lost when the highest thresholds are used. These results indicate that adjusting CSP and CSP9
336 thresholds is not an effective strategy to constraining NRT_{prot} retrievals.

337
 338
 339

Figure 4 Prototype NRT AOD pdfs over dark water surfaces from spring 2020 obtained with different CSP and CSP9 cloud-screening thresholds. Data statistics are provided in Table 2.

$N (\times 10^6)$	31.1	30.5 (-1.7%)	28.8 (-7.3 %)	28.1 (-9.7%)	26.2 (-15.6%)	25.1 (-19.2%)	FIRSTLOOK 27.9

 343
 344

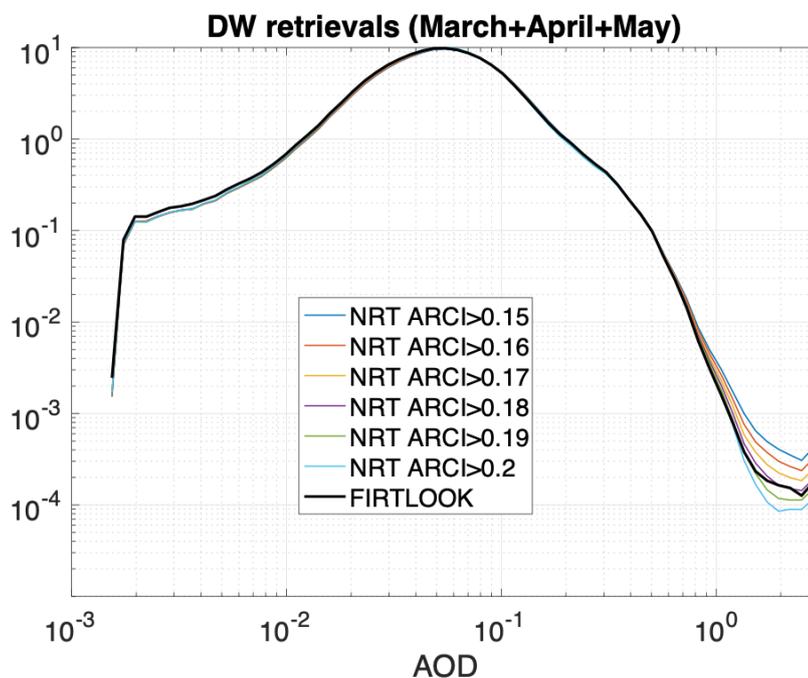

4.3.3. Sensitivity to ARCI threshold in DW retrievals

345 V23 of the MISR aerosol product introduced a new parameter, called the aerosol retrieval
 346 confidence index (ARCI), that is used to screen high-AOD retrieval outliers caused by cloud
 347 contamination and other factors (Witek et al., 2018b). ARCI, defined only for DW retrievals,

348 proved to be an efficient metric at filtering out potentially cloud-contaminated AOD retrievals. In
349 standard processing, retrievals with $ARCI < 0.15$ are removed from the recommended user
350 field, but are retained in the AUXILIARY group. The 0.15 threshold is well supported through
351 statistical analysis (Witek et al., 2018b), although some erroneous AODs still pass this
352 screening method, suggesting that increasing this threshold might be beneficial in NRT
353 processing.

354 Figure 5 and Table 3 show *pdfs* and AOD statistics for different thresholds of ARCI in the
355 NRT_{prot} product. In this case the differences between ARCI thresholds are quite noticeable,
356 especially in the high-AOD range of retrievals. Increasing the ARCI threshold to 0.2 leads to a
357 loss of about 11% of NRT_{prot} DW retrievals, but the resulting mean and geometric mean are
358 lower than the FIRSTLOOK values. At the same time, the absolute number of NRT_{prot} DW
359 retrievals (27.8 million) is still comparable to the number of FIRSTLOOK DW retrievals (27.9
360 million). The *pdfs* and the statistics suggest that increasing the NRT_{prot} ARCI threshold from
361 0.15 to 0.18 leads to a product that has similar characteristics to FIRSTLOOK.

362
363
364

Figure 5 Prototype NRT AOD pdfs from spring 2020 obtained with different ARCI thresholds. Data statistic are provided in Table 3.

$N (\times 10^6)$	31.1	30.4 (-2.2%)	29.8 (-4.3%)	29.1 (-6.5%)	28.4 (-8.7%)	27.8 (-10.8%)	Firstlook 27.9
<i>ARCI</i>	≥ 0.15	≥ 0.16	≥ 0.17	≥ 0.18	≥ 0.19	≥ 0.20	
<i>mean</i>	0.1147	0.1133	0.1120	0.1108	0.1096	0.1086	0.1105
<i>geomean</i>	0.0849	0.0841	0.0834	0.0826	0.0819	0.0812	0.0824

365 *Table 3 Additional statistic for the data presented in Fig. 5.*

366

367 **4.3.4. Recommendation for NRT processing**

368

369 The statistical analyses presented in the previous sections indicate that the lack of RCCM,
 370 SDCM, and ASCM in NRT processing has negative consequences on the product, especially by
 371 allowing more, potentially cloud-contaminated, high-AOD DW retrievals to pass screening
 372 criteria. Adjusting build-in cloud screening thresholds on CSP and CSP9 brings only limited
 373 benefits at the cost of losing a considerable percentage of retrievals. However, the ARCI
 374 threshold adjustments result in much closer statistical correspondence between the NRT_{prot} and
 375 FIRSTLOOK AOD retrievals. For that reason, a revised ARCI threshold of 0.18 is implemented
 376 in NRT processing. Since the unscreened retrievals are also provided in the AUXILIARY group
 377 of the product, users are encouraged to experiment with their own thresholds which might prove
 378 more beneficial in specific applications or geographic areas.

379

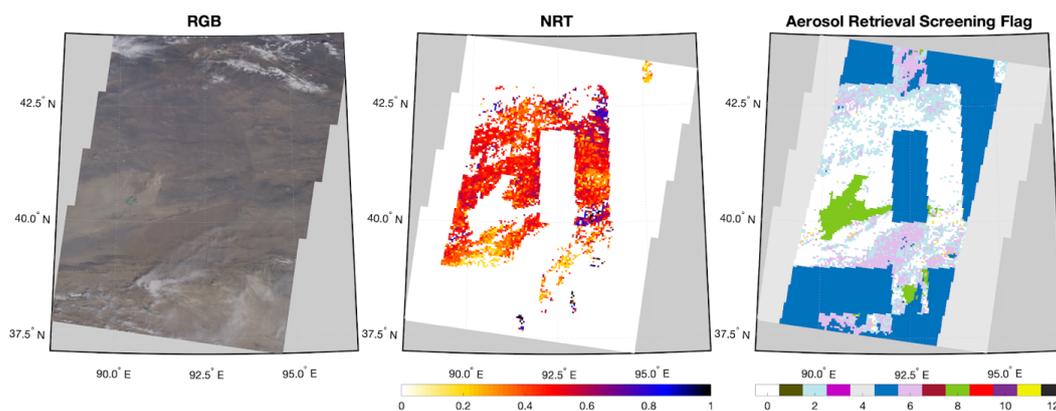

380 **4.4. Cloud/clear decision logic over snow/ice**

381

382 In section 4.1.1 the impact of upstream cloud classifiers in standard processing—namely the
 383 RCCM, SDCM, and ASCM—on the subregion’s cloud/clear designation was briefly described.
 384 The decision pathway depends on the underlying surface type, which can be either land, water,
 385 or snow/ice. Over land and water, the “cloud” outcome is only obtained when both RCCM and
 386 SDCM designate the subregion as cloudy. In the absence of RCCM and SDCM the default
 387 outcome is “clear”. Over snow/ice, however, the logic is more restrictive and favors the “cloudy”
 388 designation (Diner et al., 2008). Specifically, when the upstream cloud classifiers are not
 389 available, the subregion designation is set to “cloudy” by default. This has important implications
 390 on aerosol retrievals in areas where snow and ice occur seasonally.

391 The snow/ice surface mask, unlike land and water, is not static and changes every
392 month. Furthermore, the snow/ice mask input to MISR aerosol processing has a 1.0-degree
393 horizontal resolution, which is re-gridded to a 1.1 km resolution corresponding to the resolution
394 of MISR subregion. In standard processing, FIRSTLOOK retrievals use the snow/ice mask from
395 the same month but in the previous year. The final processing is performed when the current
396 year's monthly snow/ice mask becomes available. The NRT processing, similarly to
397 FIRSTLOOK, relies on the previous year's snow/ice mask. Additionally, given the lack of
398 upstream cloud classifiers, the snow/ice areas are designated as "cloudy" for aerosol retrieval
399 purposes. This is well visualized in Figure 6 which shows the visible image and the
400 corresponding maps of AOD and Aerosol Retrieval Screening Flag in the NRT processing. The
401 dark blue color (index 5) denotes cloudy regions determined using the snow/ice cloud logic. The
402 box-like nature of the excluded areas is associated with the coarse resolution of the snow/ice
403 mask (1.0 degree). The previous year's mask might also not be representative of the current
404 conditions on the ground. It is worth noting that the FIRSTLOOK product often suffers from the
405 same exclusion rules as NRT. This is because of the strict clear/cloud logic over snow/ice
406 surfaces which favors the cloudy outcome; in the case shown in Fig. 6 the AOD gaps in
407 FIRSTLOOK (not shown) look very similar to the NRT product.

408
409 *Figure 6 Example of snow/ice masking in NRT AOD retrievals. (Left) Visible image of the retrieval area. (Center) Corresponding*
410 *NRT AOD retrievals. (Right) NRT Aerosol Retrieval Screening Flag for the same area; the dark blue color denotes regions*
411 *designated as cloudy.*

412 Several attempts have been made by the MISR science team to improve NRT aerosol
413 retrievals in snow/ice covered areas. However, identifying and isolating snow-covered surfaces
414 in the absence of upstream cloud classifiers proves very challenging. The quality of aerosol
415 retrievals is often negatively affected in such conditions. For that reason, and in an attempt to

416 eliminate as many NRT AOD outliers as possible, the current snow/ice logic is retained in the
417 NRT aerosol processing.

418

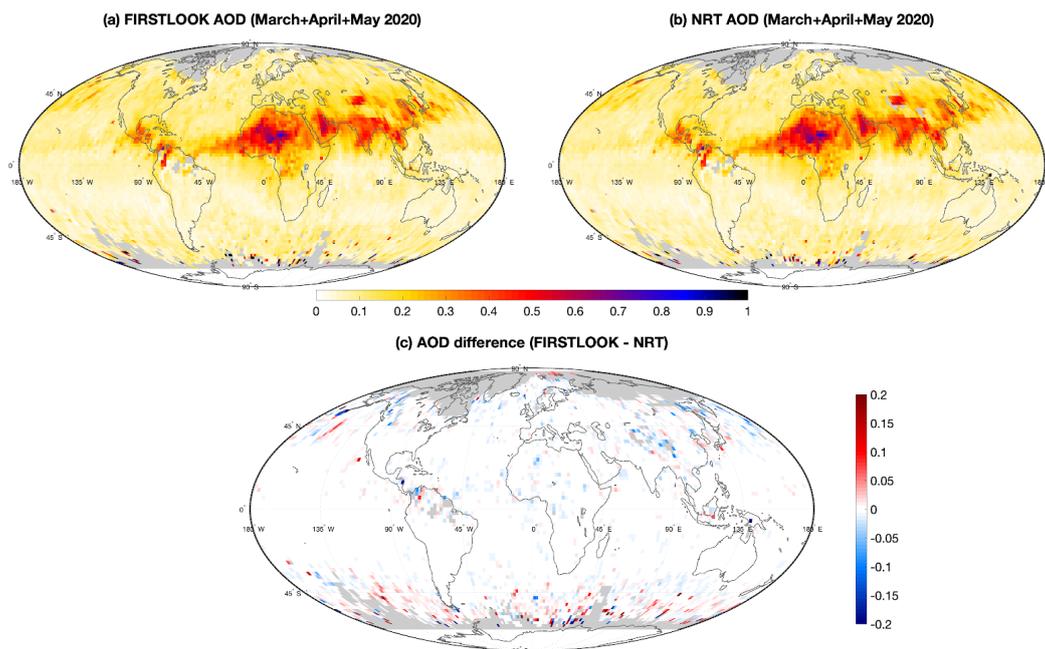

419 **5. NRT and FIRSTLOOK differences**

420

421 In this section, geographic distributions of MISR AOD retrievals from FIRSTLOOK and NRT
422 products are analyzed. The datasets encompass three months, March, April, and May of 2020.
423 The NRT AOD retrievals are screened with the revised ARCI threshold of 0.18 as suggested in
424 section 4.3.4. The spatial overlap of the FIRSTLOOK and NRT data is achieved using an
425 intersect of the X_Dim and Y_Dim fields in the two data products.

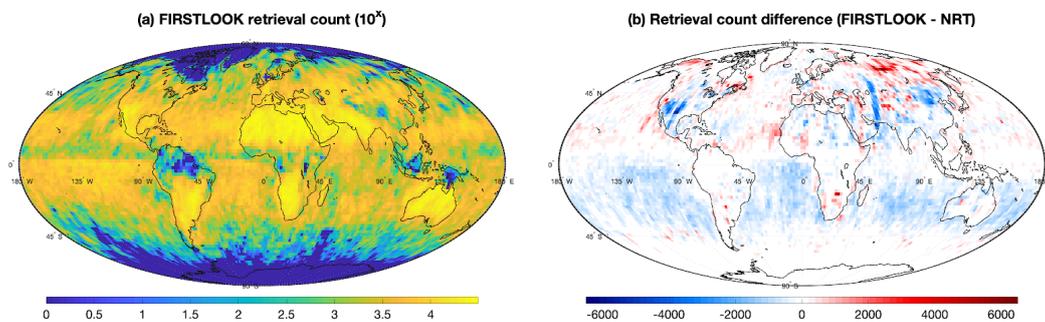

426 Figure 7 shows the global distributions of geometric mean AOD from the (a)
427 FIRSTLOOK and (b) NRT products. The retrievals are gridded at 2-by-2-degree spatial
428 resolution. Fig. 7c shows the AOD difference between the two products.

429 The largest AOD differences are seen in areas with climatologically high cloud cover,
430 especially over the Southern Ocean. In those regions the FIRSTLOOK AODs are predominantly
431 higher than the NRT AODs. This is due to the increased ARCI threshold in NRT (0.18 vs. 0.15
432 in FIRSTLOOK) which brings in more aggressive screening of cloud-contaminated retrievals
433 (Witek et al., 2018b). At the same time the lack of cloud classifiers in NRT does not adversely
434 affect AOD distributions, which is consistent with the statistical analysis presented in section
435 4.2.3.

436
437 *Figure 7 (a) Global distribution of FIRSTLOOK AOD geometric mean values across March, April, and May of 2020 on a 2-by-2-*
438 *degree spatial resolution; (b) same as in (a) but for NRT AOD; and (c) AOD difference between FIRSTLOOK and NRT.*

439 Figure 8 complements Fig. 7 by showing (a) the FIRSTLOOK retrieval count distribution
440 as well as (b) the retrieval count difference between the FIRSTLOOK and NRT products.

441
442 *Figure 8 (a) Decimal logarithm of the retrieval count from the FIRSTLOOK product in March, April, and May of 2020; (b) retrieval*
443 *count difference between FIRSTLOOK and NRT. Presented values are gridded at 2-by-2-degree spatial resolution*

444 The highest number of retrievals is found over the subtropical continents where the
445 cloud cover is usually the smallest. Over the subtropical oceans in the Southern Hemisphere the
446 NRT retrieval counts are typically lower than in FIRSTLOOK, which is attributed to the increased

447 ARCI threshold in DW retrievals. The lack of hemispheric symmetry in this case is likely due to
448 the seasonal variability (only months in northern spring are analyzed here). The conservative
449 cloud logic over snow/ice surfaces in NRT results in the lower number of retrievals in the high
450 latitudes of the northern hemisphere.

451

452 **6. Summary**

453

454 The MISR V23 aerosol product, publicly available since mid-2018, is a high-resolution state-of-
455 the-art data product from NASA's Terra flagship mission. V23 AOD retrievals have remarkable
456 accuracy compared against ground-based observations (Garay et al., 2020; Tao et al., 2020;
457 Witek et al., 2019) and the product is more intuitive and easier to use than previous versions.
458 The product is available within 2 days from satellite overpass as a FIRSTLOOK version, and
459 within 3-to-6 months as a final science-quality “standard” version that employs the most up-to-
460 date ancillary datasets. In response to the needs of operational user communities, a new MISR
461 L2 NRT aerosol product has been developed with a 3-hour latency.

462 The new NRT algorithm does not depend on the upstream cloud classifiers that are
463 generated in L1 and L2 cloud processing. The lack of cloud classifiers is in large part mitigated
464 by the aerosol algorithm’s built-in cloud identification methods. Analysis has shown an
465 increased frequency of high-AOD retrievals, especially over oceans and in climatologically
466 cloudy areas, likely due to an increase in cloud contamination. Adjusting the ARCI threshold in
467 DW retrievals proves highly effective at eliminating some of these high-AOD outliers and
468 improves the NRT product’s statistical agreement with the FIRSTLOOK version. The new NRT
469 aerosol product applies an ARCI threshold of 0.18 to mitigate cloud contamination in the
470 absence of upstream cloud masks in NRT processing. The remaining differences in statistical
471 and geographic distributions between NRT and FIRSTLOOK, which includes information from
472 the L2 cloud product, are small and largely confined to areas with high cloud cover.

473 The results of this study also serve as an example of the effects of screening threshold
474 adjustments in MISR aerosol retrievals on AOD statistics and distributions. Researchers
475 interested in particular applications and/or specific geographic regions are encouraged to
476 experiment with their own threshold to achieve most optimal results.

477

478 **Acknowledgements**

479 This research was carried out at the Jet Propulsion Laboratory, California Institute of
480 Technology, under a contract with the National Aeronautics and Space Administration. Support
481 from the MISR project is acknowledged. All data analyzed in this study are publicly available,
482 although the transient nature of FIRSTLOOK and NRT products might limit their availability. The
483 data can be downloaded from <https://l0dup05.larc.nasa.gov/cgi-bin/MISR/main.cgi>.
