10 Abstract

Long et al (2021) conducted a detailed study of possible interferents in measurements of surface O₃ by UV spectroscopy, which measures the UV transmission in ambient and O₃ scrubbed air. While we appreciate the careful work done in this analysis, there were several omissions and, in one case, the type of scrubber used was mis-identified as manganese dioxide (MnO₂), when in fact it was manganese chloride (MnCl₂). This misidentification led to the erroneous conclusion that all UV-based O₃ instruments employing solid-phase catalytic scrubbers exhibit significant positive artifacts, whereas previous research found this not to be the case when employing MnO₂ scrubber types. While the Long study, and our results, confirm the substantial bias in instruments employing an MnCl₂ scrubber, a replication of the earlier work with an MnO₂ scrubber type and no humidity correction is needed.

Introduction

20 Ozone (O₃) is a key hazardous atmospheric pollutant. In the U.S., more than 100 million people live in regions that do not meet the National Ambient Air Quality Standards. Wildfires exacerbate O₃ pollution (Jaffe et al 2013; 2020; Brey and Fischer 2016; Gong et al 2017). Given that smoke contains literally hundreds of compounds, it is important to address possible interferences in measurements of O₃. Long et al (2021) conducted a detailed study of possible interferences in UV measurements of O₃, the most commonly used method. In the UV method, O₃ is measured at 254 nm in a sample airstream and in an airstream where O₃ has been removed, usually by a solid-state catalytic scrubber. Long et al provide an excellent discussion of this method, which we won't repeat here. However, one of the most important aspects in this measurement is the nature of the scrubber that is used to remove O₃. For the scrubber, various companies have used manganese dioxide (MnO₂), Hopcalite (a mixture of manganese and copper oxides) and manganese chloride (MnCl₂). Long et al compared multiple UV instruments with an NO chemiluminescence instrument, a method which is presumably free from interferences. Long et al found a significant bias of 16–24 ppb O₃ per ppm of CO in one type of UV O₃ analyzer (Thermo-Fisher 49i) that was tested

without humidity correction, as compared to the NO-chemiluminescence method. The bias was correlated with smoke tracers, such as CO and total hydrocarbons. Other instruments were tested with a humidity correction and found to have a much smaller bias which Long et al attributed to the humidity correction. According to Long et al, the scrubber types on these instruments were similar, but in fact they were not, as discussed below, and this leads to significant uncertainty with their conclusions.

Long et al. did not cite our earlier study (Gao et al. 2017). In this work, we conducted a comparison between two UV-based O₃ analyzers (Dasibi 1008-RS and Ecotech Serinus 10) and an NO-chemiluminescent analyzer in wildfire plumes at the Mt. Bachelor Observatory (MBO) during the 2015 wildfire season. Gao found no significant bias in the UV analyzers relative to the NO-chemiluminescent analyzer in moderate smoke plumes, up to approximately 1 ppm of carbon monoxide (CO). Both of these UV analyzers used an MnO₂ scrubber. The detailed methods used in Gao's study along with the quality assurance and quality control steps are outlined in the paper and we believe these were sufficient to meet the study's objectives. A key question is: why were Long et al's results different from Gao et al's results? We address this question below.

1. Scrubber type misidentified

Long cites the Thermo-Fisher Scientific Model 49i series instrument's scrubber type as MnO₂ (as do others: Turnipseed 2017; Spicer 2010; Kleindienst 1993). However, according to a representative from the Thermo-Fisher company, the scrubbers in the 49, 49c, and 49i series use MnCl₂, not MnO₂. This was confirmed on four separate occasions by the manufacturer. This instrument was the only one used by Long et al with no humidity correction, which is the most common way these instruments are deployed.

2. Recent data from the Mt. Bachelor Observatory confirm bias with MnCl₂ scrubber type

Starting in 2018, we have deployed two O₃ instruments at the MBO, the Ecotech Serinus 10, previously used in the Gao et al study, and a Thermo-Fisher 49c, a similar instrument to the one used in Long's study which uses the same scrubber and no humidity correction. Generally, the Ecotech and Thermo-Fisher instruments agree well, but in a particularly strong period of wildfire smoke, we saw a substantial difference in the two measurements. Figure 1 shows data from a 3-week period in September–October 2020, when we experienced heavy smoke at the MBO. The slope (.0116 ppb of O₃ per ppb CO) is smaller but of the same order of magnitude as that reported by Long et al for comparisons of the Thermo-Fisher to the NO-chemiluminescent instrument (.016–.024 ppb O₃ per ppb CO). It is possible that the Ecotech also has a small degree of bias, which would explain the smaller slope compared to Long's, but it would have to be much smaller than the bias observed in the Thermo-Fisher instrument during the high CO events in 2020. Given our earlier comparison with the Ecotech instrument, we contend that this corroborates Long's conclusion that the Thermo-Fisher instrument exhibits a significant positive bias at high CO

levels. We believe the MnCl_2 scrubber in the 49i is the primary cause for the discrepancy between Long and Gao's findings.

65 3. Nafion dryer vs. scrubber impacts on O_3 measurements: need for further research

When Long et al put a Nafion dryer on their Thermo-Fisher instrument midway through the study, the bias was reduced by an order of magnitude. We agree with Long et al that the Nafion dryer reduced not only water vapor, but also probably scrubbed many of the VOC's that were causing the bias. While Nafion is known to transfer O_3 and lower molecular weight alkanes efficiently, it will remove more complex VOC's that are likely responsible for the bias in UV instruments (Perma-Pure 2022). Similar tests with/without a Nafion drier were not done for the other instruments. The Nafion-dried 2B-205 instrument in Long's study showed O_3 artifacts an order of magnitude lower than the non-dried UV analyzers, but this can be explained by the 2B's MnO_2 -containing Hopcalite scrubber acting similarly to a pure MnO_2 scrubber. We note that current EPA recommendations are to include Nafion dryers for UV O_3 instruments (Halliday et al 2020), and we see no downside to this recommendation. But given that this remains a recommendation, and to interpret past data, we suggest that future experiments include instruments with a true MnO_2 scrubber with, and without, humidity correction, as this is the most common field setup.

Data availability

Data from the Mt. Bachelor Observatory are archived at the University of Washington's Research Works Archive (https://digital.lib.washington.edu/researchworks/discover?scope=%2F&query=%22mt.+bachelor+observatory%22&submit=&filtertype_0=title&filter_relational_operator_0=contains&filter_0=data).
