## Abstract

Total gaseous chlorine (TCl<sub>g</sub>) measurements can improve our understanding of unknown sources of Cl to the atmosphere. Existing techniques for measuring TCl<sub>g</sub> have been limited to offline analysis of extracted filters and do not provide suitable temporal information on fast atmospheric process. We describe high time-resolution in-situ measurements of TCl<sub>g</sub> by thermolyzing air over a heated platinum (Pt) substrate coupled to a cavity ring-down spectrometer (CRDS). The method relies on the complete decomposition of TCl<sub>g</sub> to release Cl atoms that react to form HCl, for which detection by CRDS has previously been shown to be fast and reliable. The method was validated using custom organochlorine permeation devices (PDs) that generated gas-phase dichloromethane (DCM), 1-chlorobutane (CB), and 1,3-dichloropropene (DCP). The optimal conversion temperature and residence time through the high-temperature furnace was 825 °C and 1.5 seconds, respectively. Complete conversion was observed for six organochlorine compounds, including alkyl, allyl, and aryl C-Cl bonds, which are amongst the strongest Cl-containing bonds. The quantitative conversion of these strong C-Cl bonds suggests complete conversion of similar or

26 weaker bonds that characterize all other TCl<sub>g</sub>. We applied this technique to both outdoor and indoor  
27 environments and found reasonable agreements in ambient background mixing ratios with the sum  
28 of expected HCl from known long-lived Cl species. We measured the converted TCl<sub>g</sub> in an indoor  
29 environment during cleaning activities and observed varying levels of TCl<sub>g</sub> comparable to previous  
30 studies. The method validated here is capable of measuring in-situ TCl<sub>g</sub> and has a broad range of  
31 potential applications.

## 32 **1. Introduction**

33 Chlorine (Cl) containing compounds in the atmosphere can impact air quality, climate, and  
34 health (Saiz-Lopez and Von Glasow, 2012; Simpson et al., 2015; Massin et al., 1998; White and  
35 Martin, 2010). Gaseous chlorinated compounds are either organic (e.g., dichloromethane,  
36 chloroform, and carbon tetrachloride) or inorganic (e.g., Cl<sub>2</sub>, HCl, and ClNO<sub>2</sub>), with inorganic Cl  
37 being more reactive under most atmospheric conditions. In this work, total gaseous Cl (TCl<sub>g</sub>) refers  
38 to all gas-phase Cl-containing species weighted to their Cl content, including both inorganic and  
39 organic species. While groups of chlorinated species are often considered based on reactivity  
40 considerations (e.g., reactive chlorine, Cl<sub>y</sub>), TCl<sub>g</sub> includes all molecules that contain one or more  
41 Cl atoms:

$$42 \text{ TCl}_g = 4*[\text{CCl}_4] + 3*[\text{CHCl}_3] + 2*[\text{CH}_2\text{Cl}_2] + [\text{CH}_3\text{Cl}] + 2*[\text{Cl}_2] + [\text{HOCl}] + \dots \quad \text{E1}$$

43 Impacts on air quality and climate are due to the high reactivity of atomic Cl produced by common  
44 atmospheric reactions (e.g., photolysis and oxidation) of Cl-containing compounds (Riedel et al.,  
45 2014; Sherwen et al., 2016; Haskins et al., 2018). The Cl cycle is important to atmospheric  
46 composition in the stratosphere and troposphere, affecting species including methane, ozone, and  
47 particles (both formation and composition), which influence air quality and climate (Solomon,  
48 1999; Riedel et al., 2014; Young et al., 2014; Sherwen et al., 2016). High levels of some TCl<sub>g</sub>

49 species (e.g., Cl<sub>2</sub> and carbon tetrachloride) are known to be toxic (White and Martin, 2010; Unsal  
50 et al., 2021). The implications of many TCl<sub>g</sub> species on human health are not well understood for  
51 low level exposure for extended periods of time. Potential health impacts of organic chlorinated  
52 compounds include hepatotoxicity, nephrotoxicity, and genotoxicity (Unsal et al., 2021;  
53 Henschler, 1994). Impacts of inorganic chlorinated species include the chlorination of squalene, a  
54 major part of human skin oils, by HOCl (Schwartz-Narbonne et al., 2019); respiratory irritation  
55 and airway obstruction by Cl<sub>2</sub> (White and Martin, 2010); and increased incidence of asthma and  
56 other chronic respiratory issues following exposure to chloramines (Massin et al., 1998).

57 Sources of Cl to the atmosphere are highly variable and depend on both direct emissions  
58 and indirect regional Cl activation chemistry (Finlayson-Pitts, 1993; Raff et al., 2009; Khalil et al.,  
59 1999). Direct emissions of TCl<sub>g</sub> can come from numerous natural and anthropogenic activities  
60 such as, but not limited to, ocean and volcanic emissions, biomass burning, disinfection (i.e.,  
61 household cleaning, pool emission, etc), use of solvents and heat transfer coolants, and incineration  
62 of chlorinated wastes (Blankenship et al., 1994; Lobert et al., 1999; Keene et al., 1999; Butz et al.,  
63 2017; Wong et al., 2017; Fernando et al., 2014). Activation of Cl is another source, occurring when  
64 atmospheric processes transform relatively unreactive chloride (Cl<sup>-</sup>, such as sea salt, NaCl) into  
65 reactive gaseous chlorine (Cl<sub>y</sub>), which will contribute to TCl<sub>g</sub>. Understanding global levels of TCl<sub>g</sub>  
66 is difficult due to complex emissions and chemistry. Our best estimates come from modelling  
67 studies combined with collaborative efforts to compose policy reports on halogenated substances,  
68 such as the World Meteorological Organization (WMO) Scientific Assessment of Stratospheric  
69 Ozone Depletion (WMO (World Meteorological Organization), 2018). Mixing ratio estimates of  
70 halogenated species from this report are summed from individual measurements (e.g., National  
71 Oceanic and Atmospheric Administration (NOAA) and Advanced Global Atmospheric Gases

72 Experiment (AGAGE)). The WMO report includes flask (captured gas from clean air sectors) and  
73 in-situ measurements from field campaigns and routine sampling sites (e.g., CONvective  
74 Transport of Active Species in the Tropics (CONTRAST)) (Prinn et al., 2018; Pan et al., 2017;  
75 Andrews et al., 2016; Montzka et al., 2021; Adcock et al., 2018). In the most recent WMO report  
76 (2018), a decrease of  $12.7 \pm 0.9$  pptv Cl yr<sup>-1</sup> in total tropospheric Cl was determined for Montreal  
77 Protocol-controlled substances (e.g., chlorofluorocarbons (CFCs) and hydrochlorofluorocarbons  
78 (HCFCs)). The decrease in Montreal Protocol-controlled emissions has been slightly offset by an  
79 increase in relatively short-lived substances (e.g., dichloromethane) that are not controlled by the  
80 Montreal Protocol (WMO (World Meteorological Organization), 2018). Despite the emissions of  
81 these regulated chlorinated species being relatively well-constrained, new sources for some of  
82 these compounds have appeared in the recent past. For example, unexpected increases observed in  
83 CFC-11 emissions suggested new unreported production (WMO (World Meteorological  
84 Organization), 2018). A new source of chloroform was also recently identified and attributed to  
85 halide containing organic matter derived from penguin excrement in the Antarctic tundra (Zhang  
86 et al., 2021). Atmospheric levels of TCl<sub>g</sub> will additionally be impacted by emission sources that  
87 are relatively poorly constrained, including combustion and disinfection. Increasing levels of  
88 chlorinated species from known and unknown pathways was observed in a recent ice core study,  
89 which estimated an increase of up to 170% of Cl<sub>y</sub> (= BrCl + HCl + Cl + ClO + HOCl + ClNO<sub>3</sub> +  
90 ClNO<sub>2</sub> + ClOO + OClO + 2·Cl<sub>2</sub> + 2·Cl<sub>2</sub>O<sub>2</sub> + ICl) from preindustrial times to the 1970s could be  
91 attributed to mostly anthropogenic sources (Zhai et al., 2021).

92         Understanding TCl<sub>g</sub> source and sink chemistry is not only important for the ambient  
93 atmosphere but also for indoor environments. Uncertainty in sources and levels of chemicals,  
94 including Cl-containing compounds, indoors is related to heterogeneity in sources and individual

95 indoor environments, and the fact that relatively few studies have focused on indoor chemistry  
96 compared to outdoor. The role of chlorinated species on indoor air quality has been investigated  
97 in a few studies (Mattila et al., 2020; Wong et al., 2017; Dawe et al., 2019; Giardino and Andelman,  
98 1996; Shepherd et al., 1996; Doucette et al., 2018; Nuckols et al., 2005). Most studies have focused  
99 on cleaning with Cl-based cleaners, in which HOCl and other inorganic compounds have been  
100 observed in the gas phase at high levels (Wong et al., 2017; Wang et al., 2019; Mattila et al., 2020).  
101 Some studies have reported the presence of organic chlorinated species such as chloroform and  
102 carbon tetrachloride above bleach cleaning solutions indoors (Odabasi, 2008; Odabasi et al., 2014),  
103 and chloroform has been observed during water-based cleaning activities, such as showering and  
104 clothing washing (Nuckols et al., 2005; Shepherd et al., 1996; Giardino and Andelman, 1996).

105         Constraining the Cl budget is critical to better understanding its contributions to climate,  
106 air quality, and human health. Robust total Cl measurements are useful because it is not always  
107 feasible to routinely deploy individual measurements of the large number of known Cl-containing  
108 compounds (Table S1). As described above, estimates of  $\text{TCl}_g$  from models and summed  
109 measurements have demonstrated gaps in our knowledge. It is therefore essential to have a method  
110 capable of measuring true  $\text{TCl}_g$  to explain discrepancies between model and measured estimates  
111 due to unknown species. Measurements of total elemental composition in the condensed phase,  
112 including total Cl, have been used for monitoring and managing both known and unknown  
113 compounds (Miyake et al., 2007c, a; Yeung et al., 2008; Miyake et al., 2007b; Kannan et al., 1999;  
114 Xu et al., 2003; Kawano et al., 2007). However,  $\text{TCl}_g$  methods have been limited to offline analysis  
115 of scrubbed sample gas (e.g., flue); these methods rely on multiple extraction steps and the  
116 application of condensed-phase total Cl analyses, such as combustion ion chromatography  
117 (Miyake et al., 2007a; Kato et al., 2000) or neutron activation analysis (Berg et al., 1980; Xu et al.,

118 2006, 2007). Because offline techniques suffer from extraction uncertainties and do not have the  
119 temporal resolution to effectively probe fast chemistry in the atmosphere, in-situ measurements of  
120 total elemental gaseous composition have been developed for several elements (Hardy and Knarr,  
121 1982; Veres et al., 2010; Roberts et al., 1998; Maris et al., 2003; Yang and Fleming, 2019). For  
122 example, total nitrogen has been measured using Pt-catalyzed thermolysis coupled to online  
123 chemiluminescence detection (Stockwell et al., 2018). Using a similar approach, we describe here  
124 a method for  $\text{TCl}_g$ , where catalyzed thermolysis is coupled to a high time-resolution HCl cavity  
125 ring-down spectrometer (CRDS). This technique relies on the complete thermolysis of  $\text{TCl}_g$ , which  
126 yields chlorine atoms. These Cl atoms readily form HCl via hydrogen abstraction (R1), in this case  
127 from propane (or its thermolysis products) that is supplied in excess.

128 The objectives of this paper are to: (i) Develop and validate an instrument capable of in-  
129 situ measurement of  $\text{TCl}_g$  through conversion to HCl and detection by CRDS; and (ii) demonstrate  
130 application of the technique to outdoor and indoor  $\text{TCl}_g$  measurements.

## 131 **2. Materials and experimental methods**

### 132 **2.1. Chemicals**

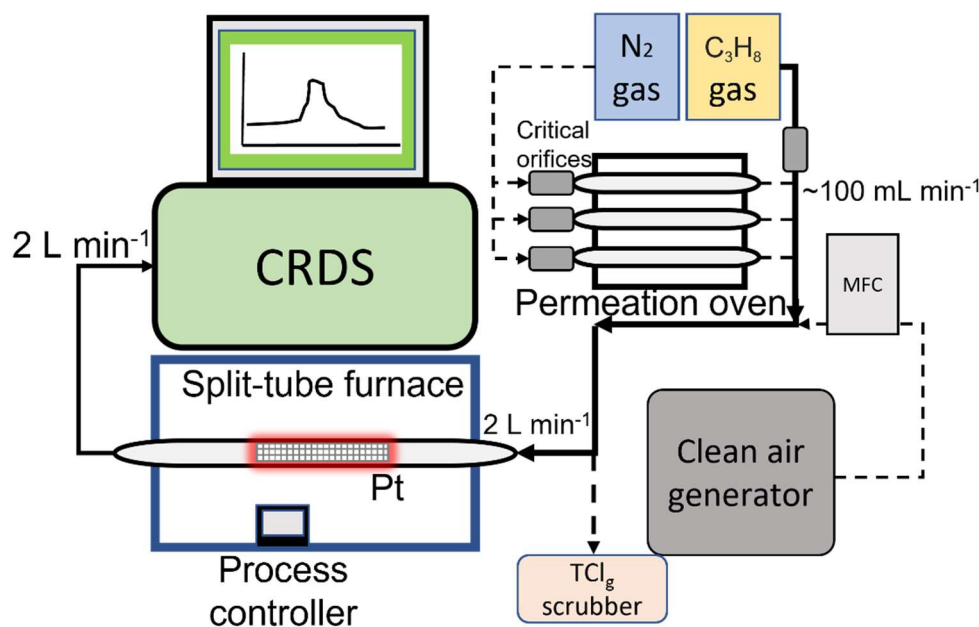

133 Commercially available reagents were purchased from Sigma-Aldrich (Oakville, Ontario,  
134 Canada): dichloromethane (DCM, HPLC grade), 1-chlorobutane (CB, 99.5%), cis-1,3-  
135 dichloropropene (DCP, 97%), trichlorobenzene (TrCB, 99%), tetrachlorobenzene (TeCB, 98%),  
136 pentachlorobenzene (PeCB, 96 %), sodium chloride, and 52 mesh sized platinum catalyst (99.9  
137 %). Toluene (HPLC grade) was purchased from BDH VWR (Mississauga, Ontario, Canada).  
138 Nitrogen (grade 4.8) and propane ( $\text{C}_3\text{H}_8$ , 12.7% in nitrogen, v/v) gas was from Praxair (Toronto,  
139 Ontario, Canada). Experiments used deionized water generated by a Barnstead Infinity Ultrapure  
140 Water System (Thermo Fisher Scientific, Waltham, Massachusetts, USA;  $18.2 \text{ M}\Omega \text{ cm}^{-1}$ ). A

141 permeation device (PD) described previously was used to generate gaseous HCl (Furlani et al.,  
142 2021). Chlorine-free zero air was generated by a custom-made zero-air generator.

## 143 **2.2. HCl and total chlorine (HCl-TCI) instrument**

144 The main components of the HCl-TCI (Figure 1) are platinum catalyst mesh, a quartz glass  
145 flow tube, a split-tube furnace (Protégé Compact, 1100°C max temperature, Thermcraft  
146 incorporated, North Carolina, USA), and a CRDS HCl analyzer (Picarro G2108 Hydrogen  
147 Chloride Gas Analyzer). The platinum catalyst consisted of ~2 g platinum mesh with a total  
148 combined surface area of 134 cm<sup>2</sup>. Sample gas was mixed with critical orifice-regulated (Lenox  
149 laser, Glen Arm, Maryland, USA, 30 psi; SS-4-VCR-2-50) propane gas (62 ± 6 standard cubic  
150 centimetres per minute (sccm)), provided in excess prior to introduction to the furnace to promote  
151 (R1). The added propane does not fully thermolyze at temperatures < 650 °C, which can lead to  
152 spectral interferences in the CRDS analyzer (Figure S1) and should only be added when  
153 temperatures exceed 650°C (Furlani et al., 2021). All lines and fittings were made of  
154 perfluoroalkoxy (PFA) unless stated otherwise. The mixing line carrying clean air dilution flows  
155 was controlled by a 10 L min<sup>-1</sup> mass flow controller (MFC, GM50A, MKS instruments, Andover,  
156 Massachusetts, USA). The length of the sample gas tubing to the furnace was 0.6 m, and the  
157 transfer line between the furnace and CRDS was 0.2 m. The furnace transfer line met an overflow  
158 tee when delivering flows greater than the CRDS flowrate of 2 L min<sup>-1</sup>. The coupled CRDS can  
159 capture transient fast HCl formation processes on the timescale of a few minutes, limited by the  
160 high adsorption activity of HCl on inlet surfaces (discussed further in Section 3.3). The CRDS  
161 collects data at 0.5 Hz. Limits of detection (LODs) for the CRDS were calculated as three times  
162 the Allan–Werle deviation in raw signal intensity when overflowing the inlet with zero air directed

163 into the CRDS for  $\sim 10$  h. The 30-sec LOD is 18 pptv and well below expected HCl from  $\text{TCI}_g$   
164 conversion (Furlani et al., 2021a).

165  
166 **Figure 1.** Sampling schematic showing the key components of the HCl-TCI coupled to the CRDS  
167 analyzer. Dashed lines indicate parts of the apparatus used only during validation. Not to scale.

### 168 2.3. Preparation of organochlorine permeation devices (PDs)

169 Organochlorine PDs were prepared as follows: approximately 200  $\mu\text{L}$  of DCM, CB, or DCP  
170 was pipetted into a 50 mm PFA tube (3 mm i.d. with 1 mm thickness), thermally sealed at one end  
171 and plugged at the other end with porous polytetrafluoroethylene (PTFE) (13 mm length by 3.17  
172 mm o.d.). The polymers allow a consistent mass of standard gas to permeate at a given temperature  
173 and pressure. The method for temperature and flow control of the PDs is described in detail in Lao  
174 et al. (2020). Briefly, an aluminum block that was temperature-controlled (Omega<sup>TM</sup>; CN 7823,  
175 Saint-Eustache, QC, Canada) using a cartridge heater (Omega<sup>TM</sup>; CIR-2081/120V, Saint-Eustache,  
176 QC, Canada) housed the PD and was regulated to  $30.0 \pm 0.1$  °C. Dry  $\text{N}_2$  gas flowed through a PFA  
177 housing tube (1.27 cm o.d.) in the block that contained the PD. Stable flows of carrier gases passed  
178 through the housing tube in the oven were achieved using a 50  $\mu\text{m}$  diameter critical orifice (Lenox

179 laser, Glen Arm, Maryland, USA, 30 psi; SS-4-VCR-2-50) and were  $120 \pm 12$ ,  $99 \pm 9.9$  and  $120$   
180  $\pm 12$  sccm for DCM, CB, and DCP, respectively. Flows were measured using a DryCal Definer  
181 220 (Mesa Labs, Lakewood, Colorado, USA). The mass emission rate of each organochlorine from  
182 the PDs was quantified gravimetrically over a period of approximately 4 weeks (mass accuracy  $\pm$   
183  $0.001$  g). Mass emission rates for each PD were determined as  $640 \pm 10$ ,  $240 \pm 40$ , and  $1.20 \times 10^4$   
184  $\pm 0.02 \times 10^4$  ng min<sup>-1</sup> (n=3,  $\pm 1\sigma$ ) at 30 °C for DCM, CB, and DCP, respectively.

#### 185 **2.4. HCl-TCl optimization**

186 Gas phase standards of DCM, CB, and DCP were used to test the conversion efficiency of  
187 chlorinated compounds to form HCl. Bond dissociation energies for carbon-Cl bonds typically  
188 range between 310 and 410 kJ mol<sup>-1</sup> (Tables S1, S2). The split-tube furnace has a process controller  
189 capable of increasing or decreasing temperature at a set °C min<sup>-1</sup>, which allowed us to identify the  
190 temperature at which enough energy was provided to break the bonds. By introducing a consistent  
191 amount of each of the organochlorines, separately, to the HCl-TCl set over a simple temperature  
192 ramping program we could monitor in real-time the conditions necessary to break the bonds by  
193 measuring the formation of the resulting HCl. The operating temperature was determined when  
194 complete conversion of the measured TCl<sub>g</sub> for the tested compounds was sustained at 100%  
195 conversion based on PD emission rates.

196 To determine the optimal residence time in the quartz tube with the Pt catalyst, flows of  
197  $0.6$ – $5.5$  L min<sup>-1</sup> containing DCM sample gas in clean air were tested yielding a range of residence  
198 times between  $0.5$  and  $4.5$  sec in the furnace. Temperature remained constant at  $825$  °C throughout  
199 the experiment, and a dilution flow of  $4.0$  L min<sup>-1</sup> of clean air was added to the sample flow exiting  
200 the furnace before introduction to the CRDS.

201 We tested the HCl transmission of the HCl-TCl at 2 mixing ratios (18 and 10 ppbv) using  
202 a 12 M HCl PD with zero air dilution flows of 3.5 or 5 L min<sup>-1</sup> using a 5 L min<sup>-1</sup> MFC (GM50A,  
203 MKS instruments, Andover, Massachusetts, USA). The HCl recovery through the furnace was  
204 tested by comparing measured HCl mixing ratios through HCl-TCl to those with the furnace flow  
205 tube replaced by a similar length of tubing. A heat gun (Master Varitemp® vt-750c) was used to  
206 heat the flow tube entrance to ~80 °C to minimize HCl sorption. We tested the HCl-TCl conversion  
207 efficiency for 5 different mixing ratios of three organochlorine PD standards (DCM, CB, and DCP)  
208 under three conditions: (1) both Pt catalyst and added propane, (2) only Pt catalyst, and (3) only  
209 added propane. Each gas was tested individually under the same conditions; sample gas from PDs  
210 was mixed with propane and immediately diluted into clean air using a 10 L min<sup>-1</sup> MFC. The  
211 dilution flows ranged from 2.2–9.0 L min<sup>-1</sup>. The sampling lines were the same lengths as stated  
212 previously. In this experiment, the CRDS flowrate of 2 L min<sup>-1</sup> was sufficient to give an optimal  
213 residence time of 1.5 sec through the HCl-TCl (see Section 3.1). In all experiments the CRDS  
214 subsampled through the furnace from the main transfer line and the excess gas was directed  
215 outdoors through a waste line containing a carbon trap (Purakol, Purafil, Inc, Doraville, Georgia,  
216 USA). We also tested the HCl-TCl conversion efficiency for two different quantities of three  
217 chlorobenzenes (TrCB, TeCB, and PeCB). Due to their high boiling points, PDs of these  
218 compounds could not be prepared. Instead, small volumes of approximately 1 mM solutions of  
219 these compounds dissolved in toluene were directly introduced to the HCl-TCl while it was  
220 sampling room air. Room air measurements of TCl<sub>g</sub> were consistently >1 ppbv. These were  
221 measured before each experiment and did not affect the peak integration described below. With a  
222 short piece of tubing used as an inlet, 1 and 2 μL of each compound was injected onto the inner  
223 surface of the tubing, which was heated to ~100 °C with a heat gun to facilitate volatilization. The

224 resulting signals were integrated over a time period of 2.5 hours to obtain the total quantity of HCl  
225 detected by the CRDS, which was used to calculate conversion efficiency. To account for  
226 uncertainties in peak integration, a high and low peak area boundary was determined, with the  
227 average peak area taken for each injection. Duplicates of each injected quantity were performed,  
228 except for 1  $\mu\text{L}$  TrCB, which was performed in triplicate.

229 To determine if there was any positive bias in the  $\text{TCl}_g$  measurement from the conversion  
230 of particulate chloride ( $\text{pCl}^-$ ), NaCl aerosols were generated by flowing  $2 \text{ L min}^{-1}$  of chlorine free  
231 zero air through a nebulizer containing a solution of 2% w/w NaCl in deionized water. The aerosol  
232 flow was then mixed with  $1 \text{ L min}^{-1}$  of chlorine free dry zero air to achieve a total flow of  $3 \text{ L}$   
233  $\text{min}^{-1}$ , The HCl-TCl ( $2 \text{ L min}^{-1}$ ) then sampled off this main mixing line. Chloride was added after  
234 monitoring background zero air levels. After  $\sim 3$  hours of measuring the converted  $\text{pCl}^-$ , a PTFE  
235 filter ( $2 \mu\text{m}$  pore size, 47 mm diameter, TISCH scientific, North Bend, Ohio, USA) was added  
236 inline onto the inlet of the HCl-TCl.

## 237 **2.5. Outdoor air HCl-TCl measurements**

238 Outdoor air sampling was performed between 00:00 on July 7 to 20:00 on July 11, 2022  
239 (Eastern daylight time, EDT). The sampling site was the air quality research station located on the  
240 roof of the Petrie Science and Engineering building at York University in Toronto, Ontario,  
241 Canada ( $43.7738^\circ \text{ N}$ ,  $79.5071^\circ \text{ W}$ , 220 m above sea level). The HCl-TCl was co-located with a  
242 Campbell Scientific weather station paired with a cr300 datalogger. All inlet lines and fittings were  
243 made of PFA unless stated otherwise. All indoor inlet lines and fittings were kept at room  
244 temperature. A mass flow controller (GM50A, MKS instruments, Andover, Massachusetts, USA)  
245 regulated a sampling flow of  $14.7 \text{ L min}^{-1}$  using a diaphragm pump through a 2.4 m sampling inlet  
246 (I.D. of 0.375") from outdoors. The outdoor air was pulled through a  $2.5 \mu\text{m}$  particulate matter

247 cut-off URG Teflon Coated Aluminum Cyclone (URG Corporation, Chapel Hill, North Carolina,  
248 USA) to remove larger particles and then passed through a PTFE filter (2  $\mu\text{m}$  pore size, 47 mm  
249 diameter, TISCH scientific, North Bend, Ohio, USA). The CRDS subsampled 2 L  $\text{min}^{-1}$  through  
250 the furnace off the main inlet line, yielding a total inlet flow of 16.7 L  $\text{min}^{-1}$ . The apparatus had  
251 zero air overflow the inlet 1 hour prior to and after outdoor sampling. The CRDS sample flow  
252 passed first through a PTFE filter (2  $\mu\text{m}$  pore size, 47 mm diameter) and then two high efficiency  
253 particulate air (HEPA) filters contained within the CRDS outer cavity metal compartment heat-  
254 regulated to 45  $^{\circ}\text{C}$ . Instances of flagged instrument errors in the CRDS data during ambient  
255 observations were removed as standard practice in quality control procedures. [The dataset can be](#)  
256 [found in Furlani et al., \(2022\).](#)

## 257 **2.6. Indoor air HCl-TCl and HOCl analyzer measurements**

258 To test indoor applications of the HCl-TCl, a 1  $\text{m}^2$  area of laboratory floor was cleaned with  
259 a commercial spray bottle cleaner (1.84 % sodium hypochlorite w/w) and emissions were  
260 compared with an HOCl analyzer. The HOCl analyzer is a commercial instrument designed to  
261 quantify gaseous hydrogen peroxide ( $\text{H}_2\text{O}_2$ ) using CRDS (Picarro PI2114 Hydrogen Peroxide  
262 Analyzer; Picarro Inc.). The instrument is also sensitive to HOCl due to similar absorbance  
263 wavelengths of their first overtone stretches in the near IR. The wavelengths monitored have been  
264 altered to selectively detect HOCl. Details on instrument calibration and validation are provided  
265 in Stubbs et al. [\(2022\)](#).

266 The distance from the suspended 2 m inlet lines of both instruments to the floor was  $\sim 1$  m.  
267 The flowrate through the furnace and inlet was the 2 L  $\text{min}^{-1}$  CRDS flowrate. The flowrate for the  
268 HOCl analyzer was 1 L  $\text{min}^{-1}$ . The sectioned off area was cleaned four times, spraying 32 times  
269 for each application using the commercial cleaner. Three of these events were measured using the

270 HCl-TCl and HOCl analyzer, while one event was measured using the HCl CRDS only. [The](#)  
271 [dataset can be found in Furlani et al., \(2022\).](#)

### 272 **3. Results and Discussion**

#### 273 **3.1. HCl-TCl temperature and residence time optimization**

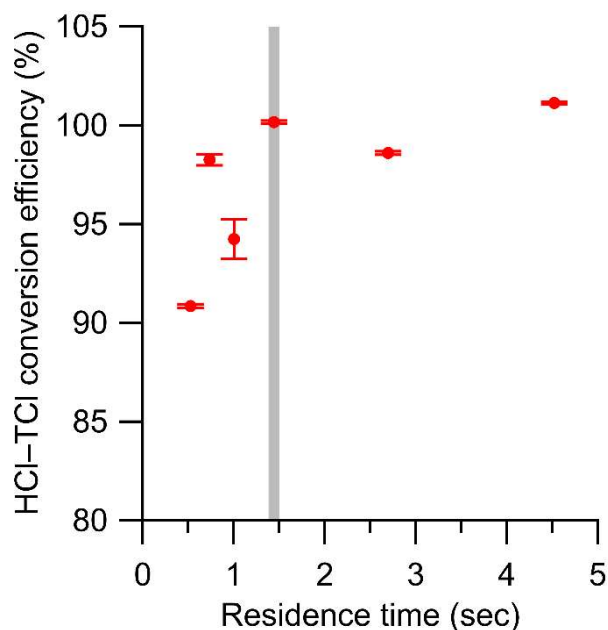

274 We validated this method by testing conversion efficiency of organochlorines under different  
275 operating parameters and conditions. Testing all TCl<sub>g</sub> species is not feasible, but by testing  
276 compounds that contain strong Cl-containing bonds, we infer at least equal efficacy of the system  
277 in the breakage of relatively weaker Cl-containing bonds (Tables S1 and S2). We selected strong  
278 Cl-containing bonds (i.e., alkyl, allyl, and aryl chlorides) and used them as a proxy for compounds  
279 containing weaker Cl bonds; therefore, by demonstrating their complete conversion we set  
280 precedent for conversion of all TCl<sub>g</sub>. The temperature of the furnace is a key factor in  
281 accomplishing complete thermolysis, and the minimum temperature of the furnace containing the  
282 Pt catalyst to break the C-Cl bonds in DCM was determined. A simple temperature ramping  
283 program was used to determine the breakthrough temperature. The temperature was increased at a  
284 rate of 2.7 °C min<sup>-1</sup> starting at 300 °C and ending at 800 °C. The temperature breakthrough was  
285 observed when complete conversion of the expected HCl for the tested compounds (based on PD  
286 emission rate) was stable after reaching the optimal temperature. It was found to be ~800 °C for  
287 the tested organochlorines (Figure S2).

288 Determining the optimal residence time of sample gas in the HCl-TCl is also essential for  
289 an optimized TCl<sub>g</sub> conversion method. Using a temperature slightly above the observed  
290 breakthrough temperature of 800 °C determined above (825 °C), six residence times were tested  
291 with DCM, ranging from 0.5 to 4.5 seconds in the HCl-TCl ([Figure 2Figure-2](#)). At each residence

292 time the conversion efficiency was determined, where conversion efficiency was calculated as  
293 follows:

$$294 \text{ Conversion efficiency} = \frac{\text{Measured TCl}_g}{\text{Expected TCl}_g} \times 100 \% \quad \text{E2}$$

295 The optimal residence time was ~1.5 seconds, corresponding to a conversion efficiency of 100.1  
296  $\pm$  0.1 %. The uncertainty in conversion efficiency measurements is the variability in the measured  
297 HCl signal for 30 minutes after a signal plateau was observed. The reported uncertainty does not  
298 include uncertainties in mixing, or turbulence induced surface effects, which we cannot quantify.  
299 When residence times were lower (i.e., sample gas traveled more quickly through the system) than  
300 1.5 seconds, the conversion efficiencies were lower by 2 – 10 %, the measured HCl signal was  
301 more erratic, and it took longer to stabilize. When residence times were higher (i.e., sample gas  
302 traveled more slowly through the system) than 1.5 seconds, the conversion efficiencies were  
303 comparable ( $\pm$  2 %), but the measured HCl suffered from longer equilibration times (~30 minutes,  
304 more than double the 1.5 residence time) and therefore a slower response time, likely due to  
305 increased surface effects of HCl after exiting the furnace. An optimal residence time of 1.5 seconds  
306 was selected for all HCl-TCl experiments for its good conversion efficiency and reasonable  
307 response time (see Table S3).

308

309 **Figure 2.** Conversion efficiency of DCM plotted against residence time in the HCl-TCl at 825 °C.  
 310 Error bars represent the percent relative standard deviation of the measured HCl by the CRDS over  
 311 ~30 minutes, after signal has plateaued. Grey vertical line denotes the selected residence time.  
 312 Note that the error bars are represented by the precision of the instrument, and we expect there  
 313 would be greater experiment-to-experiment variability.

314

### 315 **3.2. HCl-TCl conversion efficiency**

316 The efficiency of HCl throughput in the HCl-TCl was tested. Initial tests resulted in  
 317 transmission efficiencies of  $81.2\% \pm 1.4$  ( $n = 3$ ) and  $88.1\%$  ( $n = 1$ ) for 18 ppbv and 10 ppbv HCl,  
 318 respectively. At the inlet to the furnace, a small piece of the quartz tube is not heated. We  
 319 hypothesized that complete transmission of HCl was hindered through sorption to that portion of  
 320 quartz tube. Repeating the experiment with heat applied led to increased throughput efficiencies  
 321 of  $85.7\%$  (18 ppbv,  $n = 1$ ) and  $93.9\%$  (10 ppbv,  $n = 1$ ). Therefore, good HCl throughput efficiency  
 322 was demonstrated overall, with the cause of minor HCl losses identified to be sorption losses to  
 323 room temperature glass. Conversion of particulate chloride ( $pCl^-$ ) was observed to take place in  
 324 the HCl-TCl (Figure S3), but once a filter was introduced the signal returned to background levels.  
 325 Thus, to capture only gaseous  $TCl_g$  from samples that may contain particulate chloride, a

326 particulate filter should be used. Use of a filter could introduce blow on (i.e., partitioning of semi-  
327 volatile species) and/or blow off (i.e., processing of particulate chloride) artifacts. We have  
328 previously shown that HCl—likely to be the most surface active component of TCl<sub>g</sub>—is not greatly  
329 impacted by the presence of filters (Furlani et al., 2021), indicating blow on effects are likely  
330 minimal. However, the extent to which blow on effects should be considered will depend on the  
331 composition of the TCl<sub>g</sub> mixture and the temperature. Blow off effects will depend on ambient  
332 particulate chloride levels and can be mitigated by regularly changing the filter to prevent  
333 significant particulate chloride accumulation.

334 The conversion efficiency of each of the two alkyl chlorine and one allyl chlorine compounds  
335 using the HCl-TCl was tested at 5 different mixing ratios. See Table S4 for summary of mixing  
336 ratios used; all lower mixing ratios were generated by diluting the highest mixing ratio of each  
337 compound by chlorine-free zero air. All three showed good linearity and near 1:1 correlation with  
338 the HCl expected to be formed from the PD under standard operating conditions (Figure 3). Due  
339 to differences in PD emission rates, the values in Figure 3 are normalized to the highest mixing  
340 ratio to visualize comparisons more easily. With both Pt and propane the HCl-TCl conversion was  
341  $99.6 \pm 3.2$ ,  $104.8 \pm 5.6$ , and  $102.7 \pm 7.8\%$  for DCM, CB, and DCP, respectively (Table 1), as the  
342 average conversion efficiency  $\pm$  relative standard deviation. From Figure 3 the comparison  
343 between expected and measured TCl<sub>g</sub> is illustrated by near unity in the orthogonal distance  
344 regression slope ( $\pm 1\sigma$ , the error in the regression analysis), and was  $0.996 \pm 0.012$ ,  $1.048 \pm 0.060$ ,  
345 and  $1.027 \pm 0.061$  for DCM, CB, and DCP, respectively. With only the Pt catalyst, the HCl-TCl  
346 conversion was  $80.7 \pm 0.4$ ,  $54.1 \pm 1.6$ , and  $54.3 \pm 3.5\%$  for DCM, CB, and DCP, respectively  
347 (Figure S4, Table 1). This result indicates the added hydrogen source (propane) is needed to  
348 promote R1. Although necessary in this laboratory scenario, some ambient conditions may be rich

349 enough in hydrogen-containing molecules that excess propane is not needed. However, providing  
 350 propane in excess ensures the presence of an abundance of hydrogen atoms that can be readily  
 351 abstracted by Cl atoms via R1. When the Pt catalyst was removed, the HCl-TCl conversion was  
 352  $94.4 \pm 4.6$ ,  $44.2 \pm 0.9$ , and  $41.7 \pm 3.4\%$  for DCM, CB, and DCP, respectively (Figure S4, Table  
 353 1). The observed dependence of the Pt catalyst indicates that a reactive surface is important

354

355  
 356 **Figure 3.** HCl measured by CRDS plotted against the expected HCl from HCl-TCl converted  
 357 DCM (red circle), 1-chlorobutane (blue diamond), and 1,3-dichloropropene (green square) under  
 358 condition (1). All values are normalized to the highest expected HCl concentration to better  
 359 illustrate deviations from unity (black line). Error bars on the y-axis represent  $1\sigma$  in the HCl signal  
 360 over 10 minutes. Error bars on the x-axis represent the uncertainty in the PD used to generate  
 361 DCM.

362 **Table 1.** Conversion efficiency for tested Cl-containing compounds under different conditions  
 363 (both Pt and propane; Pt only; propane only). Note that chlorobenzenes were only tested under  
 364 [final](#) Pt and propane conditions.

| Tested TCl <sub>g</sub><br>species      | Cl bond<br>dissociation<br>energy (kJ mol <sup>-1</sup> ) | Conversion efficiency (%) |                |                |
|---|---|---------------------------|----------------|----------------|
|   |   | Pt and<br>propane         | Pt only        | Propane only   |
| Dichloromethane (DCM) <sup>a</sup>      | 310   | $99.6 \pm 3.2$            | $80.7 \pm 2.4$ | $94.4 \pm 6.6$ |
| 1-Chlorobutane (CB) <sup>a</sup>        | 410   | $104.8 \pm 5.6$           | $54.1 \pm 6.6$ | $44.2 \pm 5.9$ |
| 1, 3-Dichloropropene (DCP) <sup>a</sup> | 350   | $102.7 \pm 7.8$           | $54.3 \pm 5.2$ | $41.7 \pm 5.1$ |

|  |     |             |  |  |
|--|-----|-------------|--|--|
| Trichlorobenzene (TrCB) <sup>b</sup>   | 400 | 97.0 ± 19.9 |  |  |
| Tetrachlorobenzene (TeCB) <sup>b</sup> | 400 | 90.6 ± 10.3 |  |  |
| Pentachlorobenzene (PeCB) <sup>b</sup> | 400 | 90.2 ± 14.8 |  |  |

365 <sup>a</sup>Conversion efficiency was determined from the orthogonal distance regression slope and  $\pm \sigma$  and propagated error  
366 from individual permeation devices.

367 <sup>b</sup>Conversion efficiency was determined directly by the quantity (mol) of HCl measured from liquid injections of 1  
368 mM standards. The error represents  $\pm \sigma$  of measurements for n = 5 (TrCB) or n = 4 (TeCB, PeCB) injections.

369  
370 to achieve complete thermolysis at 825 °C. The relatively higher conversion for DCM in the  
371 absence of the Pt catalyst or hydrogen source may be attributed to its lower bond dissociation  
372 energy (310 kJ mol<sup>-1</sup>) compared to estimated bond dissociation energies for CB and DCP (CB  
373 inferred from Table S2 (~410 kJ mol<sup>-1</sup>), and DCP from tetrachloroethylene (350 kJ mol<sup>-1</sup> in Table  
374 S1)). It is possible that a higher temperature could lead to full conversion of TCl<sub>g</sub> in the absence  
375 of Pt catalyst; however, that was not explored in this study. To further validate the HCl-TCl, the  
376 conversion efficiency of three aryl chlorine compounds were tested under the final operating  
377 conditions (i.e., in the presence of both Pt and added propane). The TCl<sub>g</sub> measured from the three  
378 aryl compounds was unity, within the uncertainty of the measurement (Table 1).

379 The results for all six compounds show that the HCl-TCl is capable of complete conversion  
380 of mono and polychlorinated species on sp<sup>3</sup> and sp<sup>2</sup> carbons using the determined temperature and  
381 flow conditions. The complete thermolysis of the strongest C-Cl bond on the primary alkyl  
382 chloride (CB) demonstrates the efficacy of the HCl-TCl. Breaking these relatively strong C-Cl  
383 bonds, with consistent conversion efficiency across alkyl, allyl, and aryl C-Cl bonds, is a good  
384 proof of concept for complete conversion of all bonds of similar or weaker bond energies that  
385 characterize all other TCl<sub>g</sub>. To practically validate the HCl-TCl under real-world conditions with  
386 atmospherically relevant TCl<sub>g</sub> mixtures and mixing ratios we also deployed and configured the  
387 system to measure outdoor and indoor air.

### 388 3.3. Performance metrics of HCl-TCl

389 Using a flow of zero air through the HCl-TCl, method limits of detection (LODs) were  
390 calculated as three times the Allan-Werle deviation (Figure 4) when overflowing a 20 cm inlet  
391 (3.17 mm i.d.) with zero air for one hour. The LODs determined in the measurements for 2 second,  
392 1 minute, 5 minute, and 1 hour integration times were 73, 15, 10, and 8 pptv, respectively. The  
393 response time of the instrument was assessed during experiments with DCM, CB, and CP. The  
394 time for the signal to decay after removal of the PDs was determined to 37 % (1/e) and 90 % ( $t_{90}$ )  
395 of the maximum signal. The maximum time to achieve 1/e was 23 seconds, while the maximum  
396 time to achieve  $t_{90}$  was 189 seconds (Table S3). These are comparable to the response times for  
397 the HCl CRDS instrument itself (Furlani et al., 2021), suggesting the addition of the inlet furnace  
398 has a modest impact on the residence time. Given the high mixing ratios used to test the response  
399 times, we argue that under most conditions relevant to indoor and outdoor atmospheric chemistry,  
400 a sample integration time of one minute will minimize any time response effects. Data for outdoor  
401 and indoor sampling described in Sections 3.4 and 3.5 were therefore averaged to one minute.  
402 During all experiments with gaseous reagents, no evidence of catalyst performance degradation  
403 was observed.

404

405 **Figure 4.** Allan-Werle deviation ( $3\sigma$ ) in the HCl-TCl purged with zero-air (black line) shown  
406 with the ideal deviation (no drift, solid blue line) and associated error in the deviation (dashed  
407 blue line).

### 408 3.4. HCl-TCl applications to outdoor air

409 We deployed the system to measure ambient outdoor air, which we compare to the expected  
410 TCl<sub>g</sub> range from complete thermolysis of previously measured Cl-containing compounds,  
411 estimated to be between 3.3 and 19 ppbv (Table S1). Global background levels of long-lived  
412 chlorine-containing species (LLCl<sub>g</sub>) are well established (WMO (World Meteorological  
413 Organization), 2018) and were calculated by equation 3 using data from Table S1:

$$\begin{aligned} 414 \text{LLCl}_g = & 3*[\text{CCl}_3\text{F}] + 2*[\text{CCl}_2\text{F}_2] + 4*[\text{CCl}_2\text{FCCl}_2\text{F}] + 4*[\text{CCl}_3\text{CClF}_2] + 3*[\text{CCl}_3\text{CF}_3] + \\ 415 & 2*[\text{CClF}_2\text{CClF}_2] + 2*[\text{CCl}_2\text{FCF}_3] + [\text{CClF}_2\text{CF}_3] + [\text{CHClF}_2] + [\text{CH}_2\text{ClCF}_3] + 2*[\text{CH}_3\text{CCl}_2\text{F}] + \\ 416 & [\text{CBrClF}_2] + 4*[\text{CCl}_4] \quad \text{E3} \end{aligned}$$

417 A global background for LLCl<sub>g</sub> of approximately 2.6 ppbv is expected ((WMO (World  
418 Meteorological Organization), 2018), Table S1). The maximum, minimum, and median of  
419 observed ambient TCl<sub>g</sub> were 536.3, 2.0, and 3.1 ppbv, respectively (Figure 5). Measurements of  
420 HCl alone were not made during these periods but reported ranges of HCl mixing ratios for this  
421 sampling location from Furlani et al. (2021) and Angelucci et al. (2021) were typically below 110  
422 pptv, with intermittent events up to 600 pptv. [The filter present in the inlet was unlikely to have](#)  
423 [led to artifacts in this measurement. Particulate chloride is negligible in continental summertime](#)  
424 [environments](#) (Kolesar et al., 2018), [indicating blow off artifacts would be minimal. As expected,](#)  
425 [most ambient TCl<sub>g</sub> measurements were above the expected mixing ratio of LLCl<sub>g</sub>. It is possible](#)  
426 [that semi-volatile chlorinated species could have partitioned to the filter, acting as a blow on effect,](#)  
427 [and leading to an underestimate of TCl<sub>g</sub>. However, the warm temperatures during sampling \(13 to](#)  
428 [31 °C\) and high observed TCl<sub>g</sub> levels suggest this was not a large effect.](#) There is clear evidence  
429 of TCl<sub>g</sub> sources beyond LLCl<sub>g</sub> at the sampling site, with several plumes of elevated TCl<sub>g</sub>  
430 intercepted. For example, the maximum TCl<sub>g</sub> measurement (536.3 ppbv) was made in a plume just

431 after noon on July 7. Another plume was detected on July 11, with a maximum  $\text{TCI}_g$  of 42.1 ppbv.  
432 Though the purpose of this study was not to determine sources of  $\text{TCI}_g$ , we observed that plumes  
433 containing elevated  $\text{TCI}_g$  arrived from the S-SW of the sampling site, where several facilities that  
434 had reported tens to thousands of kg of yearly emissions to air of Cl-containing species are located  
435 (Figure S5).

436

437

438 **Figure 5.** Monitoring meteorological conditions and one-minute averaged  $\text{TCI}_g$  in outdoor air  
439 through HCl-TCl from July 7 to 11, 2022. Grey dashed line represents the background mixing  
440 ratio for  $\text{LLCl}_g$ .

### 441 3.5. HCl-TCl application to indoor cleaning

442 We applied a chlorine-based cleaning product four times in a well-lit indoor room and  
443 measured  $\text{TCI}_g$  using the HCl-TCl and HOCl analyzer during three of the cleaning events (Figure  
444 6). One cleaning experiment was done without the HCl-TCl and had a maximum of 370 pptv HCl.  
445 These levels are comparable to peak HCl levels of  $\sim 500$  pptv observed from surface application  
446 of bleach (Dawe et al., 2019). Consistent with previous speciated measurements (Mattila et al.,  
447 2020; Wong et al., 2017), HCl, HOCl, and  $\text{TCI}_g$  levels increased rapidly over  $\sim 5$  minutes after the  
448 application of the cleaning product. The maximum levels of  $\text{TCI}_g$  from HCl-TCl during application

449 1, 2, and 3, were 49.2, 80.0, and 69.7 ppbv, respectively. The maximum levels of HOCl from  
450 applications 1, 2, and 3, were 19.6, 24.2, and 16.8 ppbv, respectively, corresponding to 24 to 40 %  
451 of peak TCl<sub>g</sub> and 14 to 22 % of integrated TCl<sub>g</sub>. These TCl<sub>g</sub> levels were several times higher than  
452 most observed in outdoor air (Section 3.4) and were within the range expected from previous  
453 experiments (Table S1). The levels of chlorinated species observed during bleaching events is  
454 variable, between 15 to 100s of ppbv (Mattila et al., 2020; Odabasi, 2008; Wang et al., 2019; Wong  
455 et al., 2017). By comparison, our highest observed mixing ratio was 80 ppbv. Because the  
456 multiphase chemical processes involved in bleach application are complex and poorly understood,  
457 it is difficult to compare levels between similar studies, given that the underlying ambient  
458 conditions can be very different. In addition, physical parameters, such as volume of cleaning  
459 solution applied, room size, and ventilation, can all affect observed mixing ratios. For example,  
460 studies have observed that gaseous NH<sub>3</sub> partitioning into aqueous bleach can produce large and  
461 variable amounts of chloramines, NH<sub>2</sub>Cl, NHCl<sub>2</sub>, and NCl<sub>3</sub> (Mattila et al., 2020; Wong et al.,  
462 2017). In our experiments, there was on average  $82 \pm 4$  % of integrated TCl<sub>g</sub> that could not be  
463 accounted for by the HOCl measurement. Additional chlorinated species that have previously been  
464 observed to be emitted from surface bleaching include ClNO<sub>2</sub>, NH<sub>2</sub>Cl, NHCl<sub>2</sub>, NCl<sub>3</sub>, and several  
465 chlorinated organics (Odabasi, 2008; Mattila et al., 2020; Wong et al., 2017) which likely also  
466 contributed to our measured TCl<sub>g</sub>. We observed that TCl<sub>g</sub> decayed ~15% faster than the air  
467 exchange rate ( $0.72 \text{ h}^{-1}$ ), indicating additional chemical loss pathways or surface interactions  
468 (Figure S6). We observed a shorter lifetime of HOCl relative to TCl<sub>g</sub>, which is consistent with  
469 faster decay rates observed for HOCl and similar TCl<sub>g</sub> species by Wong et. al., (2017). The HOCl  
470 started decreasing after ~300 s had elapsed while the TCl<sub>g</sub> levels were still increasing. This

471 suggests that reactions involving HOCl may have led to additional TCl<sub>g</sub> species, which has been  
472 observed in laboratory studies (Wang et al., 2019).

473 In-situ measurements of TCl<sub>g</sub> could provide additional insight into sources of chlorinated  
474 species to indoor environments by creating a total inventory from which the contributions of  
475 individual measured species can be compared and used to elucidate unknown TCl<sub>g</sub> levels and  
476 mechanisms in real-time. Furthermore, several chlorinated species that have previously been  
477 observed to be emitted from surface bleaching, including Cl<sub>2</sub>, HOCl, ClNO<sub>2</sub>, NH<sub>2</sub>Cl, NHCl<sub>2</sub>, and  
478 NCl<sub>3</sub> (Mattila et al., 2020; Wong et al., 2017), have been measured by chemical ionization mass  
479 spectrometry (CIMS). Quantifying chlorinated species using CIMS remains challenging due to the  
480 required calibrations and difficulty in generating pure gas phase standards. It is therefore desirable  
481 to have a technique such as the one proposed in this study that does not require calibrations or  
482 knowledge of potential unknown TCl<sub>g</sub> species. A combination of the two methods would help  
483 constrain the total levels while still observing speciation for key TCl<sub>g</sub> species.

484

485  
 486 **Figure 6.** One-minute average HCl (purple), HOCl (orange), and TCl<sub>g</sub> (black) observed during  
 487 cleaning spray events. Mixing ratios were background corrected prior to each cleaning event. Each  
 488 subsequent application of cleaner is illustrated by a lighter shade for HOCl and TCl<sub>g</sub>.

489  
 490 **4. Conclusions**

491 In this work we developed, optimized, validated, and applied a method capable of converting  
 492 TCl<sub>g</sub> into gaseous HCl for detection by CRDS. Our TCl<sub>g</sub> measurement technique, the HCl-TCl, is  
 493 composed of a platinum catalyst mesh inside a quartz glass flow tube all contained within a split-  
 494 tube furnace. The temperature and flow rate were optimized at 825 °C and 1.5 seconds,  
 495 respectively using DCM. These conditions were validated by the complete conversion of  
 496 organochlorine compounds with strong C-Cl bonds. The HCl-TCl was used to measure TCl<sub>g</sub>  
 497 outdoors, observing a range of 2.0 to 536.3 ppbv. Levels mostly exceeded the expected background  
 498 mixing ratio of LLCl<sub>g</sub>. We also applied the HCl-TCl to an indoor environment during commercial  
 499 bleach spray cleaning events and observed varying increases in TCl<sub>g</sub> (50–80 ppbv), which was in  
 500 reasonable agreement with levels observed in previous speciated measurements. The agreement of

501 HCl-TCl outdoor and indoor measurements with available bottom-up estimates indicates its  
502 efficacy under real-world scenarios. Rapid changes in TCl<sub>g</sub> were observed in both outdoor and  
503 indoor environments indicating the utility of an in-situ technique to constrain the sources and  
504 chemistry of TCl<sub>g</sub>, as well as its impact on air quality, climate, and health. We anticipate this  
505 approach could be used in several applications, including comparisons to speciated measurements  
506 of chlorinated compounds and to further explore Cl reactivity and cycling with respect for indoor  
507 and outdoor TCl<sub>g</sub>.

### 508 **Acknowledgements**

509 We acknowledge the Sloan Foundation and Natural Sciences Engineering and Research Council  
510 of Canada for funding. We thank Melodie Lao and Yashar Iranpour for collecting air exchange  
511 rate data, Andrea Angelucci for collecting meteorological data, Dirk Verdoold for the custom  
512 quartz tube, and Chris Caputo, John Liggiio, Rob McLaren, and Trevor VandenBoer for helpful  
513 discussions. PME thanks the European Research Council. TFK is a Canada Research Chair in  
514 Environmental Analytical Chemistry. This work was undertaken, in part, thanks to funding from  
515 the Canada Research Chairs program.

### 516 **Author contributions**

517 TCF, RY, JS, and LRC collected and analyzed the data. TCF, RY, LRC, and CJY conceived of  
518 and designed the experiments with input from PME and TFK. Funding was obtained by TFK and  
519 CJY. The manuscript was written by TCF, RY, and CJY with input from all authors.
