20 **Abstract**

21 We introduce the Education and Research 3D Radiative Transfer Toolbox (EaR³T) for quantifying
22 and mitigating artifacts in atmospheric radiation science algorithms due to spatially inhomogeneous clouds
23 and surfaces, and show the benefits of automated, realistic radiance and irradiance generation along
24 extended satellite orbits, flight tracks from entire aircraft field missions, and synthetic data generation from
25 model data. EaR³T is a modularized Python package that provides high-level interfaces to automate the
26 process of 3D radiative transfer (RT) calculations. After introducing the package, we present initial findings
27 from four applications, which are intended as blueprints to future in-depth scientific studies. The first two
28 applications use EaR³T as a satellite radiance simulator for the NASA [Orbiting Carbon Observatory 2](#)
29 [\(OCO-2\)](#) and [Moderate Resolution Imaging Spectroradiometer \(MODIS\)](#) missions, which generate
30 synthetic satellite observations with 3D-RT on the basis of cloud field properties from imagery-based
31 retrievals and other input data. In the case of inhomogeneous cloud fields, we show that the synthetic
32 radiances are often inconsistent with the original radiance measurements. This lack of radiance consistency
33 points to biases in heritage imagery cloud retrievals due to sub-pixel resolution clouds and 3D-RT effects.
34 They come to light because the simulator's 3D-RT engine replicates processes in nature that conventional
35 1D-RT retrievals do not capture. We argue that 3D radiance consistency (closure) can serve as a metric for
36 assessing the performance of a cloud retrieval in presence of spatial cloud inhomogeneity even with limited
37 independent validation data. The other two applications show how airborne measured irradiance data can
38 be used to independently validate imagery-derived cloud products via radiative closure in irradiance. This
39 is accomplished by simulating downwelling irradiance from geostationary cloud retrievals of Advanced
40 Himawari Imager (AHI) along all the below-cloud aircraft flight tracks of the Cloud, Aerosol and Monsoon
41 Processes Philippines Experiment (CAMP²Ex, NASA 2019), and comparing the irradiances with the
42 collocated airborne measurements. In contrast to isolated case studies in the past, EaR³T facilitates the use
43 of observations from entire field campaigns for the statistical validation of satellite-derived irradiance. From
44 the CAMP²Ex mission, we find a low bias of 10% in the satellite-derived cloud transmittance, which we
45 are able to attribute to a combination of the coarse resolution of the geostationary imager and 3D-RT biases.
46 Finally, we apply a recently developed context-aware [Convolutional Neural Network \(CNN\)](#) cloud retrieval
47 framework to high-resolution airborne imagery from CAMP²Ex and show that the retrieved cloud optical
48 thickness fields lead to better 3D radiance consistency than the heritage independent pixel algorithm,
49 opening the door to future mitigation of 3D-RT cloud retrieval biases.

50 1. Introduction

51 Three-dimensional cloud effects in imagery-derived cloud properties have long been
52 considered an unavoidable error source when estimating the radiative effect of clouds and aerosols.
53 Consequently, research efforts involving satellite, aircraft, and surface observations in conjunction
54 with modeled clouds and radiative transfer calculations have focused on systematic bias
55 quantification under different atmospheric conditions. Barker and Liu (1995) studied the so-called
56 independent pixel approximation (IPA) bias in cloud optical thickness (COT) retrievals from
57 shortwave cloud reflectance. The bias arises when approximating the radiative transfer relating to
58 COT and measured reflectance at the pixel or cloud column level through one-dimensional (1D)
59 radiative transfer (RT) calculations, while ignoring its radiative context. However, net horizontal
60 photon transport and other effects such as shading engender column-to-column radiative
61 interactions that can only be captured in a three-dimensional (3D) framework, and can be regarded
62 as a 3D perturbation or bias relative to the 1D-RT (IPA) baseline. 3D biases affect not only cloud
63 remote sensing but they also propagate into the derived irradiance fields and cloud radiative effects
64 (CRE). Since the derivation of regional and global CRE relies heavily on satellite imagery, any
65 systematic 3D bias impacts the accuracy of the Earth's radiative budget. Likewise, imagery-based
66 aerosol remote sensing in the vicinity of clouds can be biased by net horizontal photon transport
67 (Marshak et al., 2008). Additionally, satellite shortwave spectroscopy retrievals of CO₂ mixing
68 ratio are affected by nearby clouds (Massie et al., 2017), albeit through a different physical
69 mechanism than in aerosol and cloud remote sensing (Schmidt et al., 2022).

70 Given the importance of 3D perturbations for atmospheric remote sensing, ongoing
71 research seeks to mitigate the 3D effects. Cloud tomography, for example, inverts multi-angle
72 radiances to infer the 3D cloud extinction distribution (Levis et al., 2020). This is achieved through
73 iterative adjustments to the cloud field until the calculated radiances match the observations.
74 Convolutional neural networks (CNNs, Masuda et al., 2019; Nataraja et al., 2022) account for
75 3D-RT perturbations in COT retrievals through pattern-based machine learning that operates on
76 collections of imagery pixels, rather than treating them in isolation like IPA. Unlike tomography,
77 CNNs require training based on extensive cloud-type specific synthetic data with the ground truth
78 of cloud optical properties and their associated radiances from 3D-RT calculations. Once the
79 CNNs are trained, they do not require real-time 3D-RT calculations and can therefore be useful in
80 an operational setting. Whatever the future may hold for context-aware multi-pixel or multi-sensor

81 cloud retrievals, there is a paradigm shift on the horizon that started when the radiation concept
82 for the Earth Clouds, Aerosol and Radiation Explorer (EarthCARE, Illingworth et al., 2015) was
83 first proposed (Barker et al., 2012). It foresees a closure loop where broadband radiances, along
84 with irradiance, are calculated in a 3D-RT framework from multi-sensor input fields (Barker et al.,
85 2011), and subsequently compared to independent observations by radiometers pointing in three
86 directions (nadir, forward-, and backward-viewing along the orbit). This built-in radiance closure
87 can serve as an accuracy metric for any downstream radiation products such as heating rates and
88 CRE. Any inconsistencies can be used to nudge the input fields towards the truth in subsequent
89 loop iterations akin to optimal estimation, or propagated into uncertainties of the cloud and
90 radiation products.

91 This general approach to radiative closure is also being considered for the National
92 Aeronautics and Space Administration (NASA) Atmospheric Observation System (AOS,
93 developed under the A-CCP, Aerosol and Cloud, Convection and Precipitation study), a mission
94 that is currently in its early implementation stages. Owing to its focus on studying
95 aerosol-cloud-precipitation-radiation interactions at the process level, it requires radiation
96 observables at a finer spatial resolution than achieved with missions to date. At target scales close
97 to 1 km, 3D-RT effects are much more pronounced than at the traditional 20 km scale of NASA
98 radiation products (O'Hirok and Gautier, 2005; Ham et al., 2014; Song et al., 2016; Gristey et al.,
99 2020a). Since this leads to biases beyond the desired accuracy of the radiation products, mitigation
100 of 3D-RT cloud remote sensing biases needs to be actively pursued over the next few years.

101 Transitioning to an explicit treatment of 3D-RT in operational approaches entails a new
102 generation of code architectures that can be easily configured for various instrument constellations,
103 interlink remote sensing parameters with irradiances, heating rates, and other radiative effects, and
104 can be used for automated processing of large data quantities. [A number of 3D solvers are available
105 for different purposes, for example, the I3RC \(International Intercomparison of 3D Radiation
106 Codes: Cahalan et al., 2005\) community Monte Carlo code¹, which now also includes an online
107 simulator² \(Gatebe et al., 2021\); MCarATS \(Monte Carlo Atmospheric Radiative Transfer
108 Simulator³: Iwabuchi, 2006\); MYSTIC \(Monte Carlo code for the physically correct tracing of](#)

109 photons in cloudy atmospheres: Mayer, 2009), which is embedded in libRadtran (library for
110 radiative transfer, Mayer and Kylling, 2005); McSCIA (Monte Carlo [RT] for SCIAMachy: Spada
111 et al., 2006), which is optimized for satellite radiance simulations (including limb-viewing) in a
112 spherical atmosphere; McARTIM (Deutschmann et al., 2011), with several hyperspectral
113 polarimetric applications such as differential optical absorption spectroscopy; and SHDOM
114 (Spherical Harmonic Discrete Ordinate Method⁴: Evans, 1998), which, unlike the other methods,
115 is a deterministic solver with polarimetric capabilities (Doicu et al., 2013; Emde et al., 2015) that
116 is differentiable and can therefore be used for tomography (Loveridge et al., 2022).

117 For the future operational application of 3D-RT, it is, however, desirable to run various
118 different solvers in one common architecture that automates the processing of various formats of
119 3D atmospheric input fields (including satellite data), allows the user to choose from various
120 options for atmospheric absorption and scattering, and simulates radiance and irradiance data for
121 real-world scenes. Here, we introduce one such tool that could serve as the seed for this architecture:
122 the Education and Research 3D Radiative Transfer Toolbox (EaR³T). It has been developed over
123 the past few years at the University of Colorado to automate 3D-RT calculations based on imagery
124 or model cloud fields with minimal user input. EaR³T is maintained and extended by graduate
125 students as part of their education, and applied to various different research projects including
126 machine learning for atmospheric radiation and remote sensing (Gristey et al., 2020b; 2022;
127 Nataraja et al., 2022), as well as radiative closure and satellite simulators (this paper and Schmidt
128 et al., 2022). It is implemented as a modularized Python package with various application codes
129 that combine the functionality in different ways, which, once set up, autonomously process large
130 amounts of data required by airborne and satellite remote sensing and for machine learning
131 applications.

132 The goal of the paper is to introduce EaR³T as a versatile tool for systematically quantifying
133 and mitigating 3D cloud effects in radiation science as foreseen in future missions. To do so, we
134 will first showcase EaR³T as an automated radiance simulator for two satellite instruments, the
135 Orbiting Carbon Observatory-2 (OCO-2, this application is referred to as App. 1 in this manuscript)
136 and the Moderate Resolution Imaging Spectroradiometer (MODIS, application code 2, App. 2)
137 from publicly available satellite retrieval products. In the spirit of radiance closure, the intended
138 use is the comparison of modeled radiances with the original measurements to assess the accuracy

142 of the input data, as follows: operational IPA COT products are made using 1D-RT, and thus the
143 accompanying radiances are consistent with the original measurements under that 1D-RT
144 assumption only. That is, self-consistency is assured if 1D-RT is used in both the inversion and
145 radiance simulation. However, since nature creates 3D-RT radiation fields, we break this
146 traditional symmetry in this manuscript and introduce the concept of 3D radiance consistency
147 where closure is only achieved if the original measurements are consistent with the 3D-RT (rather
148 than the 1D-RT) simulations. The level of inconsistency is then used as a metric for the magnitude
149 of 3D-RT retrieval artifacts as envisioned by the architects of the EarthCARE radiation concept
150 (Barker et al., 2012).

151 Subsequently, we discuss applications where EaR³T performs radiative closure in the
152 traditional sense, i.e., between irradiances derived from satellite products and collocated airborne
153 or ground-based observations. The aircraft Cloud, Aerosol and Monsoon Processes Philippines
154 Experiment (CAMP²Ex, Reid et al., 2022), conducted by NASA in the Philippines in 2019, serves
155 as a testbed of this approach. Here, we use EaR³T's automated processing capabilities to derive
156 irradiance from geostationary imagery cloud products and then compare these to cumulative
157 measurements made along all flight legs of the campaign (application code 3, App. 3). In contrast
158 to previous studies that often rely on a number of cases (e.g., Schmidt et al., 2010; Kindel et al.,
159 2010), we perform closure systematically for the entire data set, enabling us to identify 3D-RT
160 biases in a statistically significant manner. Finally, we apply a regionally and cloud type specific
161 CNN, introduced by Nataraja et al. (2022) that is included with the EaR³T distribution, to high-
162 resolution camera imagery from CAMP²Ex. This last example demonstrates mitigation of 3D-RT
163 biases in cloud retrievals using the concept of radiance closure to quantify its performance against
164 the baseline IPA (application code 4).

165 The general concept of EaR³T with an overview of the applications, along with the data
166 used for both parts of the paper is presented in section 2, followed by a description of the
167 procedures of EaR³T in section 3. Results for the OCO-2 and MODIS satellite simulators (part 1)
168 are shown in section 4, followed by the quantification and mitigation of 3D-RT biases with
169 CAMP²Ex data in section 5 and section 6 (part 2). A summary and conclusion are provided in
170 section 7. The code, along with the applications presented in this paper, can be downloaded from
171 the GitHub repository: <https://github.com/hong-chen/er3t>.

177 **2. Functionality and Data Flow within EaR³T**

178 **2.1 Overview**

179 To introduce EaR³T as a satellite radiance simulator tool and to demonstrate its use for the
180 quantification and mitigation of 3D cloud remote sensing biases, five applications (Figure 1) are
181 included in the [GitHub](#) software release, four of which are discussed in this paper:

224 [Nataraja et al. \(2022\)](#). In this paper, we will only provide a brief description for App. 5 in Appendix
225 [B](#). The workflow of each application consists of three parts – 1) data acquisition, 2) pre-processing,
226 and 3) RTM setup and execution. EaR³T includes functions to ingest data from various different
227 sources, e.g., satellite data from publicly available data archives, which can be combined in
228 different ways to accommodate input data depending on the application specifics. For example, in
229 [App. 1](#), EaR³T is used to automatically download and process MODIS and OCO-2 data files based
230 on the user-specified region, date and time. Building on the templates provided in the current code
231 distribution, the functionality can be extended to new spaceborne or airborne instruments. The fifth
232 column of Figure 1 shows an application that differs from the first four, and was developed for
233 earlier papers (Gristey et al., 2020a and 2020b; Nataraja et al., 2022; Gristey et al., 2022). In
234 contrast to the first four, which use imagery products as input, the fifth application ingests model
235 output from a Large Eddy Simulation (LES) and produces irradiance data for surface energy
236 budget applications, or synthetic radiance fields for training a CNN. Details and results are
237 described in the respective papers. Furthermore, Schmidt et al. (2022) builds upon [App. 1](#) to study
238 the mechanism of 3D cloud biases in OCO-2 passive spectroscopy retrievals.

239 After the required data files have been downloaded in the data acquisition step, EaR³T
240 pre-processes them and generates the optical properties of atmospheric gases, clouds, aerosols, and
241 the surface. In Figure 1, the mapping from input data to these properties is color-coded
242 component-wise (brown for associated cloud property processing if available, blue for associated
243 surface property processing if available, green for associated ground truth property). The version
244 used in this paper (v0.1.0; Chen and Schmidt, 2022) only includes MCARaTS as the 3D RT solver,
245 but others are planned for the future. MCARaTS is a radiative transfer solver uses Monte Carlo
246 photon-tracing method (Iwabuchi, 2006). It outputs radiation (radiance or irradiance) based on the
247 inputs of radiative properties of surface and atmospheric constituents (e.g., gases, aerosols, clouds)
248 such as single scattering albedo, scattering phase function, or asymmetry parameters, along with
249 solar and sensor viewing geometries. The setup of these input properties is implemented in
250 EaR³T's pre-processing steps, which translates atmospheric properties into solver-specific input
251 with minimum user intervention. To achieve this, EaR³T is modular so that it can be extended as
252 new solvers are added. Although the five specific applications in this paper do not include aerosol
253 layers, the setup of aerosol fields is fully supported and has been used in other applications (e.g.,
254 Gristey et al., 2022). After pre-processing, the optical properties are fed into the RT solver. Finally,

269

270 **Table 1:** Data variables contained in the output HDF5 file from EaR³T for radiance and irradiance calculations. The
 271 radiance is simulated with a user-specified sensor geometry at a given altitude using forward photon tracing.
 272 The data variables listed under Metadata are included for both radiance and irradiance calculations. N_x,
 273 N_y, and N_z are the number of pixels along x, y, and z direction, respectively. N_g is the number of g,
 274 explained in section 3 – [Correlated-k](#).

275

276 The aforementioned three steps – data acquisition, pre-processing, and RTM setup and
 277 execution are automated such that the 3D/1D-RT calculations can be performed for any region at
 278 any date and time using satellite or aircraft data or other data resources such as LES. EaR³T is
 279 hosted on [GitHub](https://www.github.com/hong-chen/er3t) at <https://www.github.com/hong-chen/er3t>. Since it is developed as an
 280 educational and research 3D-RT tool collection by students, it is a living code base, intended to be
 281 updated over time. The master code modules for the [five](#) applications as listed in Figure 1 are
 282 included in the EaR³T package under the `examples` directory. [In the current release \(v0.1.0\),](#)
 283 [only a limited documentation for the installation and usage, including example codes for EaR³T,](#)
 284 [are provided. More effort will be dedicated for documentation in the near-future.](#)

285

286 2.2 Data

287 The radiance simulations in [App. 1](#) and [App. 2](#) use data from the OCO-2 and MODIS Aqua
 288 instruments, both of which are in a sun-synchronous polar orbit with an early-afternoon equator
 289 crossing time within NASA’s A-Train satellite constellation. Figure 2 visualizes radiance
 290 measurements by OCO-2 in the context of MODIS Aqua imagery over a partially vegetated and

297 partially cloud-covered land, illustrating that MODIS provides imagery and scene context for
298 OCO-2, which in turn observes radiances from a narrow swath. The region is located in southwest
299 Colorado in the United States of America. We selected this case because both the surface and
300 clouds are varied along with diverse surface types. The surface features green forest and brown
301 soil, whereas clouds include small cumulus and large cumulonimbus. In addition, this scene
302 contains relatively homogeneous cloud fields in the north and inhomogeneous cloud fields in the
303 south, which allows us to evaluate the simulations from various aspects of cloud morphology. To
304 simulate the radiances of both instruments we use data products from OCO-2 and MODIS, as well
305 as reanalysis products from NASA’s Global Modeling and Assimilation Office (GMAO) sampled
306 at OCO-2 footprints and distributed along with OCO-2 data (section 2.2.2).

307

308

309 **Figure 2.** OCO-2 measured radiance (units: $\text{Wm}^{-2}\text{nm}^{-1}\text{sr}^{-1}$) at 768.52 nm, overlaid on MODIS Aqua RGB imagery
310 over southwestern Colorado (USA) on 2 September, 2019. The inset shows an enlarged portion along the
311 track, illustrating that OCO-2 radiances co-vary with MODIS-Aqua radiance observations.

312

313 For [App. 3](#) (irradiance simulations and 3D cloud bias quantification), we use geostationary
314 imagery from the Japanese Space Agency’s Advanced Himawari Imager to provide cloud
315 information in the area of the flight path of the NASA CAMP²Ex aircraft (Reid et al., 2022). The
316 AHI data are used in conjunction with aircraft measurements of shortwave spectral radiation
317 (section 2.2.4). Subsequently ([App. 4](#): 3D cloud bias mitigation), we demonstrate the concept of
318 radiance closure under partially cloudy conditions with airborne camera imagery (section 2.2.5).
319 The underlying cloud retrieval is based on a convolutional neural network (CNN), which is

322 described in a related paper (Nataraja et al., 2022) in this special issue and relies on EaR³T-
323 generated synthetic radiance data based on Large Eddy Simulations (LES).

324

325 2.2.1 Moderate Resolution Imaging Spectroradiometer (MODIS)

326 The MODIS ~~instruments are multi-use multispectral radiometers onboard~~ NASA's Terra
327 and Aqua satellites, ~~which were~~ launched in 1999 and 2002 respectively. ~~MODIS was~~ conceived
328 as a central element of the Earth Observing System (EOS, King and Platnick, 2018). For ~~App. 1~~
329 and ~~App. 2~~, EaR³T ingests MODIS level 1B radiance products at the quarter kilometer scale
330 (channels 1 and 2, ~~bands centered at 650 and 860 nm~~), MxD02QKM, where 'x' stands for 'O' in
331 the case of MODIS on Terra, and 'Y' in the case of Aqua data), the geolocation product (MxD03),
332 the level 2 cloud product (MxD06), and the surface reflectance product (MxD09A1). For this paper,
333 we use only Aqua data (MYD), from data collection 6.1. All the data are publicly available, and
334 are distributed at the LAADS (Level-1 and Atmosphere Archive & Distribution System)
335 Distributed Active Archive Center (DAAC) by NASA's Goddard Space Flight Center.

336 For cloud properties in ~~App. 2~~, we use the MODIS cloud product (MxD06L2, collection
337 6.1). It provides cloud properties such as cloud optical thickness (COT), cloud effective radius
338 (CER), cloud thermodynamic phase, cloud top height (CTH), etc. (Nakajima and King, 1990;
339 Platnick et al., 2003). Since 3D cloud effects such as horizontal photon transport are most
340 significant at small spatial scales (e.g., Song et al., 2016), we use the high-resolution red (650 nm)
341 channel 1 (250 m), and derive COT directly from the reflectance in the Level-1B data
342 (MYD02QKM) instead of using the coarser-scale operational product from MYD06. CER and
343 CTH are sourced from MYD06 and re-gridded to 250 m. The EaR³T strategy for MODIS data is
344 similar, in principle, to the more advanced method by Deneke et al. (2021), which uses a
345 ~~high-resolution wide-band visible channel from geostationary imagery to up-sample narrow-band~~
346 ~~coarse-resolution channels~~. However, we simplified cloud detection and derivation of COT from
347 reflectance data for the purpose of our paper by using a threshold method (Appendix ~~C1~~) and the
348 two-stream approximation (Appendix ~~C2~~). In future versions of EaR³T this will be upgraded to
349 more sophisticated algorithms. A simple algorithm (Appendix ~~D1~~) is used to correct for the
350 parallax shift based on the sensor geometries and cloud heights. The cloud top height data is
351 provided by the MODIS L2 cloud product and assuming cloud base is the same.

368 For the surface albedo required by the RTM, we used MYD09A1, which provides
369 cloud-cleared surface reflectance observations aggregated over an 8-day period (Vermote et al.,
370 2015). This product is available on a sinusoidal grid with a spatial resolution of 500 m for MODIS
371 band 2, and includes atmospheric correction for gas and aerosol scattering and absorption.
372 Assuming a Lambertian surface in this first release of EaR³T, we used surface reflectance as
373 surface albedo input to the RTM.

375 2.2.2 Orbiting Carbon Observatory 2 (OCO-2)

376 The OCO-2 satellite was inserted into NASA's A-Train constellation in 2014 and flies
377 about 6 minutes ahead of Aqua. OCO-2 provides the column-averaged carbon dioxide (CO₂)
378 dry-air mole fraction (XCO₂) through passive spectroscopy based on hyperspectral radiance
379 observations in three narrow wavelength regions, the Oxygen A-Band (~0.76 micron), the weak
380 CO₂ band (~1.60 micron), and the strong CO₂ band (~2.06 micron). As shown in the inset of Figure
381 2, it takes measurements in eight footprints across a narrow swath. Each of the footprints has a
382 size around 1-2 km, and the spectra for the three bands are provided by separate, co-registered
383 spectrometers (Crisp et al., 2015).

Deleted: -

384 The OCO-2 data products of 1) Level 1B calibrated and geolocated science radiance
385 spectra (L1bScND), 2) standard Level 2 geolocated XCO₂ retrievals results (L2StdND), 3)
386 meteorological parameters interpolated from GMAO (L2MetND) at OCO-2 footprint location are
387 downloaded from NASA GES DISC (Goddard Earth Science Data Archive and Information
388 Services Center) data archive (https://oco2.gesdisc.eosdis.nasa.gov/data/OCO2_DATA). Since
389 MODIS on Aqua overflies a scene 6 minutes after OCO-2, the clouds move with the wind over
390 this time period. We therefore added a wind correction on top of the parallax-corrected cloud fields
391 obtained from MODIS (section 2.2.1). This was done with the 10 m wind speed data from
392 L2MetND (see Appendix D2). For the same scene as shown in Figure 2, Figure 3 shows (a) COT,
393 (b) CER, and (c) CTH, all corrected for both parallax and wind effects (these corrections are shown
394 in Figure A2 in Appendix D). The parallax and wind corrections are imperfect as certain
395 assumptions are involved. For example, they rely on the cloud top height from the MODIS cloud
396 product. In addition, they process the whole scene with one single sensor viewing geometry. To
397 minimize artifacts introduced by the assumptions, one can apply the simulation to a smaller region.
398

408

409

410

411 **Figure 3.** (a) Cloud optical thickness derived from MODIS L1B radiance at 650 nm by the two-stream approximation
 412 (Eq. A2), (b) cloud effective radius (units: μm), and (c) cloud top height (units: km) collocated from the
 413 MODIS L2 cloud product. The locations of the cloudy pixels were shifted to account for parallax and wind
 414 effects. The parallax correction ranged from near 0 for low clouds and 1 km for high clouds (10 km CTH).
 415 The wind correction was around 0.8 km, given the average wind speed of 2 m/s to the east.

416

417 The OCO-2 data (L2StdND) themselves only provide sparse surface reflectance for the
 418 footprints that are clear, while EaR^3T requires surface albedo for the whole domain. Therefore, we
 419 used MYD09A1 as a starting point. However, since MODIS does not have a channel in the Oxygen
 420 A-Band, MODIS band 2 (860 nm) was used as a proxy for the 760 nm OCO-2 channel as follows:
 421 we collocated the OCO-2 retrieved 760 nm surface reflectance R_{OCO} within the corresponding 860
 422 nm MODIS MYD09A1 data R_{MOD} as shown in Figure 4a (same domain as Figures 2 and 3) and

423 calculated a scaling factor assuming a linear relationship between R_{OCO} and R_{MOD} ($R_{OCO} = a \cdot R_{MOD}$).
 424 Figure 4b shows R_{OCO} versus R_{MOD} for all cloud-free OCO-2 footprints. The red line shows a linear
 425 regression (derived scale factor $a=0.93$). Optionally, the OCO-2-scaled MODIS-derived surface
 426 reflectance fields can be replaced by the OCO-2 surface reflectance products for pixels where they
 427 are available. The scaled surface reflectance is then treated as surface albedo input to the RTM
 428 assuming a Lambertian surface.

Deleted: Scaling is also applied for the weak and strong CO₂ channels, even though there are matching MODIS channels.

430
 431 **Figure 4.** (a) Surface reflectance from the OCO-2 L2 product in the Oxygen A-band (near 760 nm), overlaid on the
 432 surface reflectance from the MODIS MYD09 product at 860 nm. (b) OCO-2 surface reflectance at 760 nm
 433 versus MODIS surface reflectance at 860 nm, along with linear regression ($y=ax$) as indicated by the red
 434 line (slope $a=0.9337$).

436 2.2.3 Advanced Himawari Imager (AHI)

437 The Advanced Himawari Imager (AHI, used for [App. 3](#)) is a payload on Himawari-8, a
 438 geostationary satellite operated by the Meteorological Satellite Center (MSC) of the Japanese
 439 Meteorological Agency. The AHI provides 16 channels of spectral radiance measurements from
 440 the shortwave (0.47 μ m) to the infrared (13.3 μ m). During CAMP²Ex, the NASA in-field
 441 operational team closely collaborated with the team from MSC to provide AHI satellite imagery
 442 at the highest resolution over the Philippine Sea. From the AHI imagery, the cloud product
 443 generation system - Clouds from AVHRR Extended System (CLAVR-x), was used to generate
 444 cloud products from the AHI imagery (Heidinger et al., 2014). The cloud products from CLAVR-
 445 x include cloud optical thickness, cloud effective radius, and cloud top height at 2 (at nadir) to 5

Deleted: APP

449 km spatial resolution. Since AHI provides continuous regional scans every 10 minutes the AHI
450 cloud product has a temporal resolution of 10 minutes.

451

452 2.2.4 Spectral Sunshine Pyranometer (SPN-S)

453 The SPN-S is a prototype spectral version of the commercially available global-diffuse
454 SPN1 pyranometer (Wood et al., 2017; Norgren et al., 2022). The radiometer uses a 7-detector
455 design in combination with a fixed shadow mask that enables the simultaneous measurement of
456 both diffuse and global irradiances, from which the direct component of the global irradiance is
457 calculated via subtraction. The detector measures spectral irradiance from 350 to 1000 nm, and the
458 spectrum is sampled at 1 nm resolution with 1 Hz timing.

459 During the CAMP²Ex mission, the SPN-S was mounted to the top of the NASA P-3 aircraft
460 where it sampled downwelling solar irradiance. To ensure accurate measurements, pre- and post-
461 mission laboratory-based calibrations were completed using tungsten “FEL” lamps that are
462 traceable to a National Institute of Standards and Technology standard. Additionally, the direct
463 and global irradiances were corrected for deviations of the SPN-S sensor plane from horizontal
464 that are the result of changes in the aircraft’s pitch or roll. This attitude correction applied to the
465 irradiance data is a modified version of the method outlined in Long et al. (2010). However,
466 whereas Long et al. (2010) employ a “box” flight pattern to characterize the sensor offset angles,
467 in this study an aggregation of flight data containing aircraft heading changes under clear-sky
468 conditions are used as a substitute. The estimated uncertainty of the SPN-S system is 6 to 8%, with
469 4 to 6% uncertainty stemming from the radiometric lamp calibration process, and up to another 2%
470 resulting from insufficient knowledge of the sensor cosine response. The stability of the system
471 under operating conditions is 0.5%. A thorough description of the SPN-S and its calibration and
472 correction procedures is provided in Norgren et al. (2022). In this paper (App. 3) only the global
473 downwelling irradiance sampled by the 745 nm channel is used.

474

475 2.2.5 Airborne All-Sky Camera (ASC)

476 The All-Sky Camera (used for App. 4) is a commercially available camera (ALCOR
477 ALPHEA 6.0CW⁵) with fish-eye optics for hemispheric imaging. It has a Charge-Coupled Device

last accessed on April 24, 2022.

481 (CCD) detector that measures radiances in red, green, and blue channels. Radiometric and
482 geometric calibrations were performed at the Laboratory of Atmospheric and Space Physics at the
483 University of Colorado Boulder. The three-color channels are centered at 493, 555, and 626 nm
484 for blue, green, and red, respectively, with bandwidths of 50 – 100 nm. Only radiance data from
485 the red channel ~~are~~ used in this paper. The spatial resolution of the ASC depends on the altitude of
486 the aircraft and the viewing zenith angle. Across the hemispheric field of view of the camera, the
487 resolution of the field angle is approximately constant, at about 0.09° . At a flight level of 5 km,
488 this translates to a spatial resolution of 8 m at nadir. However, due to accuracy limitations of the
489 geometric calibration and the navigational data from Inertial Navigation System (INS), the nadir
490 geolocation accuracy could only be verified to within ± 50 m. During the CAMP²Ex flights, the
491 camera exposure time was set manually to minimize saturation of the detector. The standard image
492 frame rate is 1 Hz. The precision of the camera radiances is on the order of 1%, and the radiometric
493 accuracy is 6 – 7%.

494

495 3. EaR³T Procedures

496 In the previous section, we described the general workflow of EaR³T applications, along
497 with relevant data. In this section, we will focus on the specific implementation of the workflow
498 through the EaR³T software package. It is a toolbox for 3D-RT with modules for automatic input
499 data download and processing, generation of radiative and optical properties of surface,
500 atmospheric gases, clouds and aerosols, wrappers for 3D-RT solvers and output post-processing,
501 with the end goal to simulate radiances and irradiances along entire satellite orbits or aircraft flight
502 tracks. Unlike established radiative transfer packages such as libRadtran (Mayer and Kylling, 2005;
503 Emde et al., 2016), which provide extensive libraries of optical properties along with a selection
504 of solvers, EaR³T focuses on automated radiative transfer for two- or three-dimensional cloud,
505 aerosol, and surface input data, and therefore only comes with minimal options for optical
506 properties, and solvers. The initial release ([version 0.1.0](https://github.com/hong-chen/er3t)) is available at <https://github.com/hong-chen/er3t>.

508 We will now walk through the OCO-2 and MODIS simulator applications with the codes
509 `examples/01_oco2_rad-sim.py` ([App. 1](#)) and `examples/02_modis_rad-sim.py`
510 ([App. 2](#)). The data acquisition (first step in Figure 1) uses functions in `er3t/util.App.1` and

Deleted: were

Deleted: APP

Deleted: APP

Deleted: APP

515 [App. 2](#) use the functions in `er3t/util/modis.py` and `er3t/util/oco2.py` for
516 downloading the MODIS and OCO-2 data files from the respective NASA data archives and for
517 processing the data (e.g., geo-mapping, gridding etc.). The user supplies minimum input (date and
518 time, as well as latitudes and longitudes of the region of interest), which need to be specified in
519 `download_modis_https` and `download_oco2_https` (from `er3t/util`). For
520 example, for [App. 1](#) and [App. 2](#), the only user inputs are the date and time and the region of interest
521 – in this case September 2, 2019, with the westernmost, easternmost, southernmost, and
522 northernmost longitudes and latitudes of 109°W, 107°W, 37°N, and 39°N. In order for EaR³T to
523 access any data archives such as NASA Earthdata, the user needs to create an account with them
524 and store the credentials locally (detailed instructions are provided separately along with the EaR³T
525 distribution).

526 After the data acquisition step, the satellite data are fed into the pre-processing step for 1)
527 atmospheric gases (`er3t/pre/atm`), 2) clouds (`er3t/pre/cld`), 3) surface
528 (`er3t/pre/sfc`) as shown in Figure 1. In the default configuration of the [App. 1](#), the standard
529 US atmosphere (Anderson et al., 1986; included in the EaR³T repository) is used within `atm`.
530 EaR³T supports the input of user-specified atmospheric profiles, e.g., atmospheric profiles from
531 reanalysis data for [App. 2](#) as described in Schmidt et al. (2022), by making changes in
532 `atm_atmmod` (from `er3t/pre/atm`). Subsequently, molecular scattering coefficients are
533 calculated by `cal_mol_ext` (from `er3t/util`), and absorption coefficients for atmospheric
534 gases are generated by (`er3t/pre/abs`). At the current development stage, two options are
535 available:

- 536 1. Line-by-line (used by [App. 1](#)): The repository includes a sample file of absorption coefficient
537 profiles for a subset of wavelengths within OCO-2’s Oxygen A-Band channel, corresponding
538 to a range of atmospheric transmittance values from low (opaque) to high (so-
539 called “continuum” wavelength). They were generated by an external code (Schmidt et al.,
540 2022) based on OCO-2’s line-by-line absorption coefficient database (ABSCO, Payne et al.,
541 2020). For each [OCO-2 spectrometer wavelength within a given channel](#), hundreds of
542 individual absorption coefficient profiles, at the native resolution of ABSCO, [need to be](#)
543 [considered](#) across the instrument line shape (ILS, also known as the slit function) of the
544 spectrometer. The ILS, as well as the incident solar irradiance, are also included in the file.
545 In subsequent steps, EaR³T performs RT calculations at the native spectral resolution of

Deleted: APP

Deleted: oco

Deleted: APP

Deleted: APP

Deleted: APP

Deleted: APP

Deleted: APP

Deleted: there are

Deleted: , spectrally spaced

Deleted: , and ranging

Deleted: OCO-2 Oxygen A-Band

557 ABSCO, but then combines the output by convolving with the ILS and outputs OCO-2
558 radiances or reflectances at the subset of wavelengths. For probabilistic (Monte Carlo) RT
559 solvers such as MCARaTS, the number of photons can be kept relatively low (e.g., 10⁶
560 photons), and can be adjusted according to the values of the ILS at a particular ABSCO
561 wavelength. Any uncertainty at the ABSCO spectral resolution due to photon noise is greatly
562 reduced by convolving with the ILS for the final output.

563 2. Correlated-k (used by [App. 2](#)): This approach (Mlawer et al., 1997) is appropriate for
564 instruments such as MODIS with much coarser spectral resolution than OCO-2, as well as
565 for broadband calculations. In contrast to the line-by-line approach, RT calculations are not
566 performed at the native resolution of the absorption database, but at Gaussian quadrature
567 points (called “g’s”) that represent the full range of sorted absorption coefficients, and then
568 combined using Gaussian quadrature weights. The repository includes an absorption
569 database from Coddington et al. (2008), developed specifically for a radiometer with
570 moderate spectral resolution on the basis of HITRAN (high-resolution transmission
571 molecular absorption database) 2004 (Rothman et al., 2005). It was created for the ILS of
572 the airborne Solar Spectral Flux Radiometer (SSFR, Pilewskie et al., 2003), but is applied to
573 MODIS here, which has a moderate spectral resolution of 8-12 nm with 20-50 nm
574 bandwidths. It uses 16 absorption coefficient bins (g’s) per target wavelength ([this could](#)
575 [either be an individual SSFR or a MODIS channel](#)), which are calculated by EaR³T with the
576 Coddington et al. (2008) database using the mixing ratios of atmospheric gases in the
577 previously ingested profile. In future implementations, the code will be updated to enable
578 flexible ILS and broadband calculations.

579 The `er3t/pre/cld` module calculates extinction, thermodynamic phase, and effective
580 droplet radius of clouds from the input data. The `er3t/pre/pha` module creates the required
581 single scattering albedo and scattering phase function. The default is a Henyey-Greenstein phase
582 function with a fixed asymmetry parameter of 0.85. [Along with the current distribution \(v0.1.0\) of](#)
583 [EaR³T, the Mie phase functions based on thermodynamic phase, effective droplet radius, and](#)
584 [wavelength are supported](#). In this study, [App. 1](#) and [App. 2](#) use Mie phase functions calculated
585 from Legendre polynomial coefficients ([originally distributed along with libRadtran](#)) based on the
586 wavelength and cloud droplet effective radius. In the future, EaR³T will include stand-alone phase
587 functions, which can be chosen on the basis of droplet size distributions in addition to effective

Deleted: APP

Deleted: It is, however, recommended to also install libRadtran to...

Deleted: enable the usage of

Formatted: Superscript

Deleted: APP

Deleted: APP

594 radius. It is also possible to include aerosols in a similar fashion as clouds. This is done with the
595 `er3t/pre/aer` module. In the case of aerosols, spectral single scattering albedo and asymmetry
596 parameter are required as inputs in addition to the extinction fields.

597 After the optical properties are calculated, they are passed into the 3D-RT step
598 (`er3t/rtm/mca`). In addition to MCARaTS, planned solvers for the future include MYSTIC
599 (Monte Carlo code for the physically correct tracing of photons in cloudy atmospheres, Mayer,
600 2009) and SHDOM (Spherical Harmonic Discrete Ordinate Method, Evans, 1998; Pincus and
601 Evans, 2009). This step performs the setup of RT solver-specified input parameters and data files,
602 distributing runs over multiple [Central Processing Units \(CPUs\)](#), and post-processing RT output
603 files into a single, user-friendly HDF5 file. For example, when radiance is specified as output
604 (default in [App. 1](#) and [App. 2](#)), key information such as the radiance field and its standard deviation
605 are stored in the final HDF5 file (details see Table 1).

606 While the EaR³T repository comes with various applications such as [App. 1](#) and [App. 2](#),
607 described above, the functions used by these master or ‘wrapper’ programs can be organized in
608 different ways, where the existing applications serve as templates for a quick start when developing
609 new applications. The functions used by the master code pass information through the various
610 steps as Python objects. For example, in `examples/01_oco2_rad-sim.py`, the downloaded
611 and processed satellite data are stored into the `sat` object. Later, the `sat` object is passed into an
612 EaR³T function to create the `cld` object that contains cloud optical properties. Similarly, EaR³T
613 provides functions to create the `atm`, and `sfc` objects with optical properties for atmospheric
614 gases and the surface. These objects (`atm`, `cld`, `sfc`) are in turn passed on to solver-specific
615 modules for performing RT calculations. The user can choose to save the data of the intermediate
616 objects into Python pickle files after the first run. In this way, multiple calls with identical input
617 can re-use existing data, which accelerates the processing time of EaR³T. Unless the user specifies
618 the `overwrite` keyword argument in the object call to reject saving pickle files, these shortcuts
619 save significant time. Moreover, EaR³T is capable of distributing simulations over multiple CPUs
620 to accelerate the calculations, which is useful for potential future application of later EaR³T or
621 EaR³T-like codes in operational or large-scale data processing.

622 In the following sections, we discuss results obtained from EaR³T, starting with those from
623 `examples/01_oco2_rad-sim.py` and `examples/02_modis_rad-sim.py` (section
624 4), `examples/03_spns_flux-sim.py` (section 5), and concluding with

632 `examples/04_cam_nadir_rad-sim.py` (section 6). The detailed RT setup for the
633 applications is provided [Table A1 in Appendix A](#).

635

636 4. EaR³T as a 3D Satellite Radiance Simulator

637 This section demonstrates the automated 3D radiance simulation for satellite instruments
638 by EaR³T for OCO-2 and MODIS measured radiance based on publicly available MODIS retrieval
639 products. The OCO-2 application is an example of radiance consistency between two distinct
640 satellite instruments where the measurements of one (here, OCO-2) are compared with the
641 simulations based on data products from the other (here, MODIS). The MODIS application, on
642 the other hand, is an example of radiance self-consistency. We will show how inconsistencies can
643 be used for detecting cloud and surface property retrieval biases.

644 4.1 OCO-2 ([App. 1](#))

645 The OCO-2 radiance measurements at 768.52 nm for our sample scene in the context of
646 MODIS imagery were shown in Figure 2. For that track segment, Figure 5a shows the simulated
647 radiance along with the measurements as a function of latitude. The radiance was averaged over
648 every 0.01° latitude window from 37° N to 39° N (the standard deviation within the bin indicated
649 by the shaded color). In clear-sky regions (e.g., around 38.2° N), the simulations (red) are
650 systematically higher than the measurements (black), even though the footprint-level OCO-2
651 retrieval was used to scale the MYD09 [surface reflectance](#) field as described in section 2.2.2
652 (Figure 4). This is because, unlike the MYD09 algorithm which relies on multiple overpasses and
653 multiple-days for cloud-clearing, the OCO-2 retrieval is done for any clear footprint. Clouds in the
654 vicinity lead to enhanced diffuse illumination that is erroneously attributed to the surface
655 reflectance itself. The EaR³T IPA calculations of the clear-sky pixels (blue) essentially reverse the
656 3D effect and therefore match the observations better. The 3D calculations enhance the reflectance
657 through the very same 3D cloud effects that led to the enhanced surface illumination in the first
658 place. It is possible to correct this effect by down-scaling the surface reflectance according to the
659 ratio between clear-sky 3D and IPA calculations, but this process is currently not automated.

Figure 5. (a) Latitudinally averaged (0.01° spacing) radiance calculations from EaR³T (red: 3D, blue: IPA) and OCO-2 measured radiance at 768.52 nm (black). The green shaded area indicates the inset shown in (b). (b) The same as Figure 2 except OCO-2 measured radiance overlaid on IPA radiance simulations at 768.52 nm. The solar zenith angle (SZA) for the radiance simulation case is 33.57°.

In the cloudy locations, the IPA calculations match the OCO-2 observations on a footprint-by-footprint level (see Figure 5b), demonstrating that wind and parallax corrections were performed successfully. Of course, there is not always a perfect agreement because of morphological changes in the cloud field over the course of six minutes. It is, however, apparent that the 3D calculations agree to a much lesser extent with the observations than the IPA calculations. Just like the mismatch for the clear-sky pixels indicates a bias in the input surface reflectance, the bias here means that the input cloud properties (most importantly COT) are inaccurate. For most of the reflectance peaks, the 3D simulations are too low, which means that

682 the input COT is biased low. This is due to 3D cloud effects on the MODIS-based cloud retrieval.
683 Since they are done with IPA, any net horizontal photon transport is not considered, which leads
684 to an apparent surface brightening as noted above, at the expense of the cloud brightness. As a
685 result, the COT from darker clouds is significantly underestimated. This commonly known
686 problem ([Barker and Liu, 1995](#)), with several aspects discussed in the subsequent EaR³T
687 applications, can be identified by radiance consistency checks such as the one shown in Figure 5,
688 and mitigated by novel types of cloud retrievals that do take horizontal photon transport into
689 account (section 6).

690

691 4.2 MODIS ([App. 2](#))

692 To go beyond the OCO-2 track and understand the bias between simulated and observed
693 radiances from a domain perspective, we now consider the radiance simulations for the MODIS
694 650 nm channel. The setup is exactly the same as for the OCO-2 simulations, except that 1) the
695 viewing zenith angle is set to the average viewing zenith angle of MODIS within the shown domain
696 (instead of OCO-2), and 2) the surface reflectances from MYD09 are used directly, this time from
697 the 650 nm channel without rescaling. Figure 6a shows the MODIS measured radiance field, while
698 Figure 6b shows the EaR³T 3D simulations. Visually, the clouds from the EaR³T simulation are
699 generally darker than the observed clouds, which is in line with our aforementioned explanation
700 of net horizontal photon transport. They are also blurrier because radiative smoothing (Marshak et
701 al., 1995) propagates into the retrieved COT fields, which are subsequently used as input to EaR³T.
702 To look at darkening and smoothing effects more quantitatively, Figure 7 shows a heatmap plot of
703 simulated radiance versus observed radiance. It shows that the radiance for cloud-covered pixels
704 (labeled “cloudy”) from EaR³T are mostly low-biased while good agreement between simulations
705 and observations was achieved for clear-sky radiance (labeled “clear-sky”). The good agreement
706 over clear-sky regions is expected. As mentioned above, we use MYD09 as surface reflectance
707 input, which in contrast to the OCO-2 surface reflectance product is appropriately cloud-screened
708 and therefore does not have a reflectance high bias. There is, of course, a reflectance enhancement
709 in the vicinity of clouds, but that is captured by the EaR³T calculations. The fact that the
710 calculations agree with the observations even for clear-sky pixels in the vicinity of clouds, shows
711 that the concept of radiance consistency works to ensure correct satellite retrievals even in [the](#)
712 presence of clouds. It also corroborates our observation from section 4.1 that COT_{IPA} is low biased.

Deleted: APP

714 Since the MODIS reflectance is *not* self-consistent with respect to COT_{IPA} as shown for the *cloudy*
 715 pixels in Figure 7, we can identify a bias in the cloud properties even without knowing the ground
 716 truth of COT. On the other hand, successful closure in radiance (self-consistency) would provide
 717 an indication that the input fields including COT are accurate, although it is certainly a weaker
 718 metric than direct verification of the retrievals through aircraft satellite retrieval validation with
 719 in-situ instruments.

720

721

722 **Figure 6.** (a) MODIS measured radiance in channel 1 (650 nm). (b) Simulated 3D radiance at 650 nm from EaR³T.

723

The solar zenith angle for the radiance simulation case is 34.42°.

724

725

726

727 **Figure 7.** Heatmap plot of EaR³T simulated 3D radiance vs. MODIS measured radiance at 650 nm.

728

729 Summarizing the two satellite radiance simulator applications, one can say that EaR³T
730 enables a radiance consistency check for inhomogeneous cloud scenes. We demonstrated that a
731 lack of simulation-observation consistency (MODIS versus OCO-2) and self-consistency (MODIS
732 versus MODIS) can be traced back to biased surface reflectance or cloud fields in the simulator
733 input. This can become a diagnostic tool for the quality of retrieval products from future or current
734 missions, even when the ground truth is not known. It should be pointed out that the vertical extent
735 of the clouds affects the simulated radiance – the larger the vertical extent, the larger the 3D effects
736 (more horizontal photon transport). Since we make the assumption of a cloud geometric thickness
737 of 1 km if no thickness information is provided, the simulated radiance at the satellite sensor level
738 is valid for that proxy cloud only. For deeper clouds, the simulated radiance would be even lower.
739 Either way, the comparison with the actual radiance measurements will reveal a lack of closure.
740 Additionally, although the clouds introduce the lion’s share of the 3D bias that is identified by the
741 radiance consistency check, additional discrepancies can be introduced in different ways. For
742 example, the topography (mountainous region in Colorado) is not considered by MCARaTS (it is
743 considered by MYSTIC, but this solver has not been implemented yet).

744 For technical reference: The MODIS simulation (domain size of [Nx=1188, Ny=1188])
745 took about one hour on a Linux workstation with 12 CPUs for three 3D RT runs with 10⁸ photons
746 each. With a slightly modified setup and parallelization, the automation can be easily applied for
747 entire satellite orbits, although more research is required to optimize the computation speed
748 depending on the desired output accuracy.

749
750 **5. EaR³T as 3D Aircraft Irradiance Simulator (App. 3)**

751 In contrast to the previous applications that focused on satellite remote sensing, we will
752 now be applying EaR³T to quantify 3D cloud retrieval biases through direct, systematic validation
753 of imagery-derived *irradiances* against aircraft measurements, instead of using the indirect path
754 of radiance consistency in section 4. Previous studies (e.g., Schmidt et al., 2007; Kindel et al.,
755 2010) conducted radiative closure between remote sensing derived and measured irradiance using
756 isolated flight legs as case studies. Here, with the efficiency afforded by the automated nature of
757 EaR³T, we are able to conduct radiative closure of irradiance through a statistical approach that
758 employs campaign-scale amounts of measurement data. Specifically, we used EaR³T to perform
759 large-scale downwelling irradiance simulations at 745 nm based on geostationary cloud retrievals

Deleted: APP

761 from AHI for the CAMP²Ex campaign, and directly compare these simulations to the SPN-S
762 measured irradiances onboard the P-3 aircraft. This is done for all below-cloud legs from the entire
763 campaign with the aim to assess the degree to which satellite-derived near-surface irradiances
764 reproduce the true conditions below clouds.

765 The irradiance simulation process is similar to the previously described radiance simulation
766 in section 4, with only a few modifications. First, we used cloud optical properties from the AHI
767 cloud product (COT, CER and CTH) as direct inputs into EaR³T. Secondly, we used a constant
768 ocean surface reflectance value of 0.03. Such simplification in surface albedo is made under the
769 assumption that 1) the ocean surface is calm with no whitecaps, and that 2) the Lambertian
770 bidirectional reflectance distribution function (BRDF) is sufficient (instead of directionally
771 dependent BRDF) to represent surface albedo for the irradiance calculation. Since the ocean
772 surface albedo can greatly differ from 0.03 when the Sun is extremely low (Li et al., 2006), we
773 excluded data under low-Sun conditions where the SZA is greater than 45°. Lastly, since EaR³T
774 can only perform 3D simulations for a domain at a single specified solar geometry, we divided
775 each CAMP²Ex research flight into small flight track segments where each segment contains 6
776 minutes of flight time. The size and shape of the flight track segments can vary significantly due
777 to the aircraft maneuvers, aircraft direction, aircraft speed, etc. For each flight track segment,
778 EaR³T performs irradiance simulations for a domain that extends half a degree at an averaged solar
779 zenith angle. In contrast to the radiance simulation output, which is two-dimensional at a specified
780 altitude and sensor geometry, the irradiance simulation output is three dimensional. In addition to
781 x (longitude) and y (latitude) vectors, it has a vertical dimension along z (altitude). From the
782 simulated three-dimensional irradiance field, the irradiance for the flight track segment is [linearly](#)
783 interpolated to the x-y-z location (longitude, latitude, and altitude) of the aircraft. EaR³T
784 automatically sub-divides the flight track into tiles encompassing track segments, and extracts the
785 necessary information from the aircraft navigational data. Based on the aircraft time and position,
786 EaR³T downloads the AHI cloud product that is closest in time and space to the domain containing
787 the flight track segment.

788 Figure 8 shows [the](#) simulated irradiance for a sample flight track below clouds on 20
789 September, 2019. Figure 8a shows the flight track overlaid on AHI imagery. Figure 8b shows 3D
790 (in red) and IPA (in blue) downwelling irradiance simulations for the highlighted flight track in
791 Figure 8a, as well as measurements by the SPN-S (in black). Since the 3D and IPA simulations

792 are performed separately at discrete solar and sensor geometries for each flight track segment based
793 on potentially changing cloud fields from one geostationary satellite image to the next,
794 discontinuities in the calculations (indicated by gray dashed lines) are expected. The diffuse
795 irradiance (downwelling and upwelling) can also be simulated and compared with radiometer
796 measurements (not shown here). Since the irradiance was simulated/measured below clouds, high
797 values of downwelling irradiance indicate thin-cloud or cloud-free regions while low values of
798 downwelling irradiance indicate thick-cloud regions. The simulations successfully captured this
799 general behavior – clouds thickened from west to east until around 121.25° E, and thinned
800 eastwards. However, the fine-scale variabilities in irradiance were not captured by the simulations
801 due to the coarse resolution of COT in the AHI cloud product (3-5 km). Additionally, the
802 simulations also missed the clear-sky regions in the very east and west of the flight track as
803 indicated by high downwelling irradiance values measured by SPN-S. This is probably also due to
804 the coarse resolution of the AHI COT product where small cloud gaps are not represented. Large
805 discrepancies between simulations and observations occur in the mid-section of the flight track
806 where clouds are present (e.g., longitude range from 121.15° to 121.3°). Although the 3D
807 calculations differ somewhat from the IPA results, they are both biased high, likely because the
808 input COT (the IPA-retrieved AHI product) is biased low. This bias is caused by the same
809 mechanism that was discussed earlier in the [MODIS](#) examples (section 4.2). This begs the question
810 whether this is true for the entire field mission. To answer the question, we performed a *systematic*
811 comparison of the cloud transmittance for *all* available below-cloud flight tracks from CAMP²Ex,
812 using EaR³T's automated processing pipeline. [The output of this pipeline is visualized in time-](#)

825

826 **Figure 8.** (a) Flight track overlay HIMAWARI AHI RGB imagery over the Philippine Sea on 20 September, 2019.

827 The thin line shows the entire flight track within the domain. The thick line highlights the specific leg
 828 analyzed in (b). (b) Measured downwelling irradiance from SPN-S at 745 nm and calculated 3D and IPA
 829 irradiance from EaR³T for the highlighted flight track in (a).

830

831 For this comparison, we use transmittance instead of irradiance. The transmittance is
 832 calculated by dividing the downwelling irradiance below clouds (F_{\downarrow}^{bottom}) by the downwelling
 833 irradiance at the top of the atmosphere extracted from the Kurucz solar spectra (F_{\downarrow}^{TOA} ; Kurucz,
 834 1992) at incident solar zenith angle (SZA), where Transmittance =
 835 $F_{\downarrow}^{bottom} / (F_{\downarrow}^{TOA} \cdot \cos(SZA))$. Thus the transmittance has less diurnal dependence than the
 836 irradiance. Figure 9 shows the histograms of the simulated and measured cloud transmittance from
 837 all below-cloud legs. The average values are indicated by dashed lines. Although the averaged
 838 values of IPA and 3D transmittance are close, their distributions are different. Only the 3D
 839 calculations and the measured transmittance reach values beyond 1. This occurs in clear-sky
 840 regions in the vicinity of clouds that receive photons scattered by the clouds as previously
 841 discussed for the OCO-2 application.

842

Deleted: because it has less diurnal dependence

845
 846 **Figure 9.** Histogram of measured transmittance from SPN-S at 745 nm (black) and calculated 3D (red) and IPA (blue)
 847 transmittance from EaR³T for all the below-cloud flight tracks during CAMP²Ex in 2019. The mean values
 848 are indicated by dashed lines. The yellow (green) shaded area represents the relatively low (high)
 849 transmittance region where the probability density of the observed transmittance (black) is greater than the
 850 calculations. ▼

Deleted: Vice versa for the green shaded area.

851
 852 Both the distribution and the mean value of the simulations are different from the
 853 observations – the simulation histograms peak at around 0.9 while the observation histogram peaks
 854 at around 1. The histograms indicate that the RT simulations miss most of the clear-sky conditions
 855 because of the coarse resolution of the AHI cloud product. If clouds underfill a pixel, AHI
 856 interprets the pixel as cloudy in most cases. This leads to an underestimation of clear-sky regions
 857 since cumulus and high cirrus were ubiquitous during CAMP²Ex. The area on the left (highlighted
 858 in yellow) has low cloud transmittance associated with thick clouds. In this range, the histograms
 859 of the calculations are generally below the observations, and the PDF of the calculations is offset
 860 to the right (indicated by the yellow arrow). This means that the transmittance is overestimated by
 861 both IPA and 3D RT, and thus that the COT of thick clouds is underestimated, consistent with
 862 what we found before (Figure 8b). The high-transmittance end (highlighted in green) is associated
 863 with clear-sky and thin clouds. Here, the peak of the PDF is shifted to the left (green arrow), and
 864 the calculations are biased low. This is caused by a combination of 1) the overestimation in COT
 865 of thin clouds due a 3D bias in the AHI IPA retrieval, 2) the aforementioned resolution effect that
 866 underestimates the occurrence of clear-sky regions (or overestimation in cloud fraction), and 3)
 867 net horizontal photon transport from clouds into clear-sky pixels. Overall, the calculations
 868 underestimate the true transmittance by 10%. This might seem to contradict Figure 7, where the

Deleted: histogram

Deleted: s

Deleted: Overall, the low bias dominates, as is apparent from mean values of the distributions. There is an overall low bias of 10%, and the combined imager resolution and 3D effects do not compensate each other.

876 calculated reflected radiance was biased low due to the *underestimation* of COT in the heritage
877 retrievals, which would correspond to an *overestimation* of the radiation transmitted by clouds.
878 This effect is indeed apparent in the yellow-shaded area of Figure 9 (high COTs), but the means
879 (dashed lines) show exactly the opposite. To understand that, one has to consider that the histogram
880 depicts all-sky conditions, which include both cloudy and clear pixels. In this case, the direction
881 of the overall (all-sky) bias follows the direction of the thin-cloud/clear bias, rather than the
882 direction of the thick cloud bias. For different study regions of the globe with different cloud
883 fractions, cloud size distributions, and possibly different imager resolutions, the direction and
884 magnitude of the bias might be very different.

885 Summarizing, this application demonstrates that the EaR³T's automation feature allows
886 systematic simulation-to-observation comparisons. If aircraft observations are available, then
887 closure between satellite-derived irradiance and suborbital measurements is a more powerful
888 verification of satellite cloud retrieval products than the radiance consistency from the earlier
889 stand-alone satellite applications. Even more powerful is the new approach to process the data
890 from an entire field mission for assessing the quality of cloud products in a region of interest (in
891 this case, the CAMP²Ex area of operation).

893 **6. EaR³T for Mitigating 3D Cloud Retrieval Biases (App. 4)**

894 In this section, we will use high-resolution imagery from a radiometrically calibrated
895 all-sky camera flown during the CAMP²Ex to isolate the 3D bias (sometimes referred to as IPA
896 bias) and explore its mitigation with a newly developed CNN cloud retrieval framework (Nataraja
897 et al., 2022). The CNN, unlike IPA, takes pixel-to-pixel net horizontal photon transport into
898 account. It exploits the spatial context of pixels in cloud radiance imagery, and extracts a higher-
899 dimensional, multi-scale representation of the radiance to retrieve COT fields as the output. It does
900 so by learning on "training data", which in this case was input radiance and COT pairs synthetically
901 generated by EaR³T using LES data from the Sulu Sea. The best CNN model, trained on different
902 coarsened resolutions of the data pairs, is included within the EaR³T repository. For App. 4, this
903 CNN is applied to real imagery data for the first time, which in our case are near-nadir observations
904 by the all-sky camera (section 2.2.5) that flew in CAMP²Ex.

905 The CNN model was trained at a single (fixed) sun-sensor geometry (solar zenith angle,
906 $SAZ=29.2^\circ$; solar azimuth angle, $SAA=323.8^\circ$, viewing zenith angle, $VZA=0^\circ$), at a spatial

Deleted: We found that the bias between observed and satellite-derived cloud transmittance is partially caused by the coarse imager resolution, and partially by 3D effects, although other retrieval artifacts could also play a role. Although important for future research, it is beyond the scope of this paper to disentangle these effects.

917 resolution of 100 m. We therefore chose a camera scene with a matching SZA (28.9°), and rotated
 918 the radiance imagery to match $SAA=323.8^\circ$, and subsequently gridded the 8-12 m native
 919 resolution camera data to 100 m. Figure 10a shows the RGB imagery captured by the all-sky
 920 camera over the Philippine Sea at 02:10:06 UTC on 5 October 2019. The Sun is located at the
 921 southeast (as indicated by the yellow arrow) and can be easily identified from the sun glint. Note
 922 that this image has not yet been geolocated; it is depicted as acquired in the aircraft reference frame.
 923 Figure 10b shows the rotated scene of the red channel radiance for the region encircled in yellow
 924 in Figure 10a. The sun (as indicated by the yellow arrow) is now at $SAA=323.8^\circ$. The selected
 925 study region is indicated by the red rectangle in Figure 10b ($6.4 \times 6.4 \text{ km}^2$), where the raw radiance
 926 of the camera is gridded at 100 m resolution to match the spatial resolution of the training dataset
 927 of the CNN.

930
 931 **Figure 10.** (a) RGB imagery of nadir-viewing all-sky camera deployed during CAMP²Ex for a cloud scene centered
 932 at $[123.392^\circ\text{E}, 15.2744^\circ\text{N}]$ over the Philippine Sea at 02:10:06 UTC on 5 October, 2019. The arrows
 933 indicate the true north (green), flight direction (blue), and illumination (where the sunlight comes from,

957 fields, which are visually quite different. For relatively ~~thin~~ clouds (e.g., at ~~around {2, 1.8}~~), the
 958 CNN tends to retrieve larger COT values than COT_{IPA} . Also, it returns more spatial structure than
 959 the IPA (e.g., around {2,-1}). To assess how either retrieval performs, we now apply the radiance
 960 self-consistency approach introduced with MODIS data in section 4.2. Using both the IPA and the
 961 CNN retrieval as input, we had EaR³T calculate the (synthetic) radiance that the camera should
 962 have observed if the retrieval were accurate. The clouds are assumed to be located at 1-2 km. Such
 963 an assumption is inferred from low-level aircraft observations of clouds on the same day. These
 964 radiance fields are shown in Figure 12a and 12b, and can be compared to ~~Figure 12c, Seven~~ edge
 965 pixels have been removed from the original domain, because the CNN performs poorly at edge
 966 pixels, and because the 3D calculations use periodic boundary conditions.

Figure 13. Scatter plot overlays 2D histogram of 3D radiance calculations at 600 nm based on cloud optical thickness (a) estimated by IPA and (b) predicted by the CNN vs. measured red channel radiance from all-sky camera.

Deleted: Two-Stream approximation

As evident from the brightest pixels in Figures 12b and 12c, the radiances simulated on the basis of the CNN COT input are markedly lower than actually observed by the camera. This is because the CNN was trained on a LES dataset with limited COT range that excluded the largest COT that occurred in practice. This means that the observational data went beyond the original training envelope of the CNN, which highlights the importance of choosing the CNN training data carefully for a given region. In Figure 13, the simulations are directly compared with the original observations, confirming that indeed the CNN-generated data are below the observations on the high radiance end. Otherwise, the CNN-generated radiances agree with the observations. In contrast, the IPA-generated data are systematically lower than the observations, over the dynamic range of the COT, which is indicative of the 3D retrieval bias that we discussed earlier. Here again, the self-consistency approach proves useful despite the absence of ground truth data for the COT. This is extremely helpful because in reality satellite remote sensing does not have the ground truth of COT, whereas radiance measurements are always available. For the CNN, the self-consistency of the radiance is remarkable for the thinner clouds (radiance smaller than 0.4), which encompass 83.5% of the total number of image pixels.

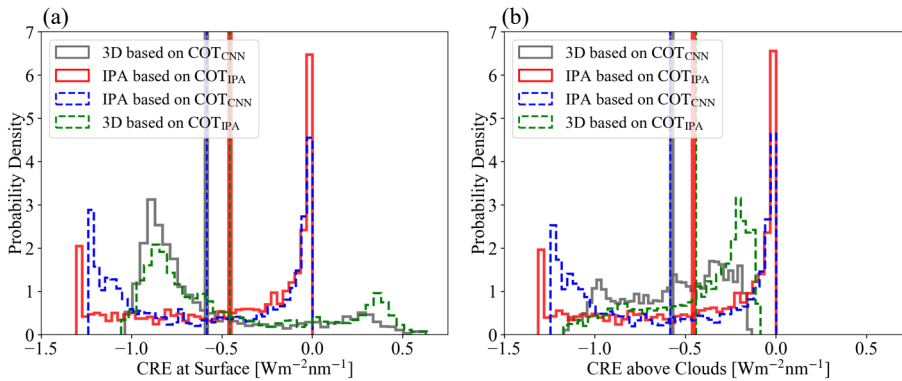

Deleted: 10b

Deleted: By

Finally, we use EaR³T to propagate the 3D cloud retrieval bias into the associated bias in estimating the cloud radiative effect from passive imagery retrievals, which means that we are returning from a remote sensing to an energy perspective (irradiance) at the end of the paper. The calculated cloud radiative effects (CRE) of both below-clouds (at the surface) and above-clouds

1028 (at 3 km) are shown in Figure 14a and 14b. The most important histograms are those from 3D
 1029 irradiance calculations based on the CNN retrievals (gray solid line), as this combination would
 1030 be used in a next-generation framework for deriving CRE from passive remote sensing, and the
 1031 other would be IPA irradiance calculations based on the IPA retrieval (red solid line), as done in
 1032 the traditional (heritage) approach. The dashed lines are the other combinations. The mean values
 1033 (red vs. gray) indicate that in our case the traditional approach would lead to a high bias of more
 1034 than to 25% both at the surface and above clouds. Here again, 3D biases do not cancel each other
 1035 out in the domain average. If the CNN had better fidelity even for optically thick clouds, the real
 1036 bias in CRE would be even larger. A minor, but interesting finding is that regardless of which COT
 1037 retrieval is used, the mean CRE is very similar for IPA and 3D irradiance calculations (e.g.,
 1038 $CRE_{IPA}(COT_{CNN}) \approx CRE_{3D}(COT_{CNN})$; blue dashed line overlay gray solid line), even though the
 1039 PDFs are very dissimilar. By far the largest impact on accuracy comes from the retrieval technique,
 1040 not from the subsequent CRE calculations. Here again, the self-consistency check turns out as a
 1041 powerful metric to assess retrieval accuracy. Of course, we only used a single case in this part of
 1042 the paper. For future evaluation of the CNN versus the IPA, one would need to process larger
 1043 quantities of data in an automated fashion as done in the first part of the paper. This is beyond the
 1044 scope of this introductory paper, and will be included in future releases of EaR³T and the CNN.

1055 **7. Summary and Conclusion**

1056 In this paper, we introduced EaR³T, a toolbox that provides high-level interfaces to
1057 automate and facilitate 1D- and 3D-RT calculations. We presented applications that used EaR³T
1058 to:

- 1059 a) build a processing pipeline that can automatically simulate 3D radiance fields for satellite
1060 instruments (currently OCO-2 and MODIS) from publicly available satellite surface and
1061 cloud products at any given time over any specific region;
- 1062 b) build a processing pipeline that can automatically simulate irradiance along all flight legs
1063 of aircraft missions, based on geostationary cloud products;
- 1064 c) simulate radiance and irradiance for high-resolution COT fields retrieved from an airborne
1065 camera, using both a traditional 1D-RT (IPA) approach, and a newly developed 3D-RT
1066 (CNN) approach that considers the spatial context of a pixel.

1067 Unlike other satellite simulators that employ 1D-RT, EaR³T is capable of performing the radiance
1068 and irradiance calculations in 3D-RT mode. Optionally, it can be turned off to link back to
1069 traditional 1D-RT codes, and to calculate 3D perturbations by considering the changes of 3D-RT
1070 fields relative to the 1D-RT baseline.

1071 With the processing pipeline under a) ([App. 1](#) and [App. 2](#), section 4), we prototyped a
1072 3D-RT powered radiance loop that is envisioned for upcoming satellite missions such as
1073 EarthCARE and AOS. Retrieved cloud fields (in our case, from MODIS and from an airborne
1074 camera) are fed back into a 3D-RT simulation engine to calculate at-sensor radiances, which are
1075 then compared with the original measurements. Beyond currently included sensors, others can be
1076 added easily, taking advantage of the modular design of EaR³T. This radiance closure loop
1077 facilitates the evaluation of passive imagery products, especially under spatially inhomogeneous
1078 cloud conditions. The automation of EaR³T permits calculations at any time and over any given
1079 region, and statistics can be built by looping over entire orbits as necessary. The concept of
1080 radiance consistency could be valuable even for existing imagery datasets because it allows the
1081 automated quantification of 3D-RT biases even without ground truth such as airborne irradiance
1082 from suborbital activities. In the future it should be possible to include a 3D-RT pipeline such as
1083 EaR³T into operational processing of satellite derived data products.

1084 Benefitting from the automation of EaR³T in b) ([App. 3](#), section 5), we performed 3D-RT
1085 irradiance calculations for the entire CAMP²Ex field campaign, moving well beyond radiation

1090 closure case studies, and instead systematically evaluating satellite-derived radiation fields with
1091 aircraft data for an entire region. From the comparison based on all below-cloud flight tracks
1092 during the entire campaign, we found that the satellite-derived cloud transmittance was biased low
1093 by 10% compared to the observations when relying on the heritage satellite cloud product.

1094 From the statistical results of the CAMP²Ex irradiance closure in b), we concluded that the
1095 bias between satellite-derived irradiances and the ground truth from aircraft measurements was
1096 due to a combination of the coarse spatial resolution of the geostationary imagery products, and
1097 3D-RT effects. To minimize the coarse-resolution part of the bias and thus to isolate the 3D-RT
1098 bias, we used high-resolution airborne camera imagery in c) (App. 4, section 6), and found that
1099 even with increased imager resolution, biases persisted. The at-sensor radiance derived from IPA
1100 COT retrievals was inconsistent with the original measurements. For cloudy pixels, the calculated
1101 radiance was well below the observations, confirming an overall low bias in IPA COT. This low
1102 bias could be largely mitigated with the context-aware CNN developed separately in Nataraja et
1103 al. (2022) and included in EaR³T. Of course, this novel technique has limitations. For example,
1104 the camera reflectance data went beyond the CNN training envelope, which would need to be
1105 extended to larger COT in the future. In addition, the CNN only reproduces two-dimensional
1106 clouds fields and does not provide access to the vertical dimension, which will be the next frontier
1107 to tackle. Still, the greatly improved radiance consistency from COT_{IPA} to COT_{CNN} indicates that
1108 the EaR³T-LES-CNN approach shows great promise for the mitigation of 3D-RT biases associated
1109 with heritage cloud retrievals. We also discovered that for this particular case, the CRE calculated
1110 from traditional 1D cloud products can introduce a warm bias of at least 25% at the surface and
1111 above clouds.

1112 EaR³T has proven to be capable of facilitating 3D-RT calculations for both remote sensing
1113 and radiative energy studies. Beyond the applications described in this paper, EaR³T has already
1114 been extensively used by a series of on-going research projects such as producing massive 3D-RT
1115 calculations as training data for a new generation of CNN models (Nataraja et al., 2022), evaluating
1116 3D cloud radiative effects associated with aerosols (Gristey et al., 2022), creating flight track and
1117 satellite track simulations for mission planning etc. More importantly, the strategies provided in
1118 this paper put novel machine learning algorithms on a physical footing, opening the door for the
1119 mitigation of complexity-induced biases in the near-future. More development effort will be
1120 invested into EaR³T in the future, with the goals of minimizing the barriers to using 3D-RT

1126 calculations, and to promote 3D cloud studies. EaR³T will continue to be an educational tool driven
1127 by graduate students. In the future, we plan to add support for additional publicly available 3D RT
1128 solvers, e.g., SHDOM, as well as built-in support for HITRAN and associated correlated-k
1129 methods. From a research perspective, we anticipate that EaR³T will enable the systematic
1130 quantification and mitigation of 3D-RT biases of imagery-derived cloud-aerosol radiative effects,
1131 and may be the starting point for operational use of 3D-RT for future satellite missions.

Appendix A - Technical Input Parameters of EaR³T

EaR³T provides various functions that can be combined to tailored pipelines for automatic 3D radiative transfer (3D-RT) calculations as described App. 1 – 5 of this paper (App. 1 – 5), as well as for complex research projects beyond. Since EaR³T is written in Python, the modules and functions can be integrated into existing functions developed by the users themselves. Parallelization is enabled in EaR³T by default through multi-processing to accelerate computations. If multiple CPUs are available, EaR³T will distribute jobs for the 3D RT calculations. By default, the maximum number of CPUs will be used. Since EaR³T is designed to make the process of setting up and running 3D-RT calculations simple, some parameters that are unavailable from the input data but are required by the RT solvers are populated via default values and assumptions. However, this does not mean that by using EaR³T, one must use these assumptions; they can be easily superseded by user-provided settings. To facilitate this process, Table A1 provides a detailed list of parameters (subject to change in future updates) that can be controlled and modified by the user. In `examples/02_modis_rad-sim.py`, we defined these user-controllable parameters as global variables for providing easy access to user. In the future, most of the parameters will be controllable through a dedicated configuration file for optimal transparency. These parameters can be changed within the code. For instance, by changing the parameters of `_date` (Line 67 in `examples/02_modis_rad-sim.py`) and `region` (Line 68 in `examples/02_modis_rad-sim.py`) into the following:

```
date = datetime.datetime(2022, 2, 10)
region = [-6.8, -2.8, 17.0, 21.0]
```

one can perform similar RT calculations (as demonstrated in App. 2) for another date and region of interest (here, west Sahara Desert on 10 February, 2022). Note that the cloud detection algorithms we included in the code are imperfect (they only work satisfactorily for the App. 2 case we presented in this paper); for other regions on the globe, they may need to be adjusted. Automation of this feature is planned for the future. In addition, intuitive and simple examples are provided in `examples/00_er3t_mca.py` and `examples/00_er3t_lrt.py` for users who are interested in learning the basics of setting up EaR³T for calculations. At the current stage, only limited documentation is provided. However, community support is available from the author of this paper through Discord⁶. In the near-future, more effort will be invested into documentation

⁶ <https://discord.gg/ntqsguwaWv>

1165 to give the user more autonomy in creating new applications that cannot be derived from those
 1166 provided in our paper.

1169 **Table A1:** List of parameters used in the five applications. The line numbers used in the table are referring to the code
1170 script of each application. If two line numbers are provided, the first one indicates where the parameter is
1171 defined and the second one indicates where the parameter is passed into the radiative transfer setup. Users
1172 can change either one for customization purposes.

1173
1174 **Appendix B – App. 5 Radiance calculations based on the Large Eddy Simulation**

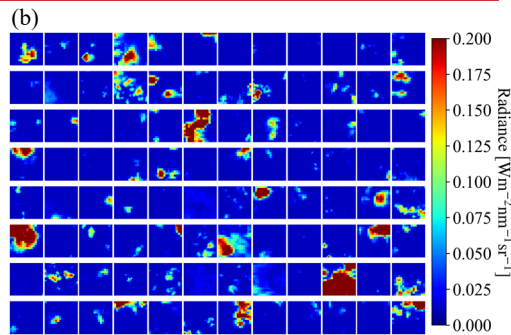

1175 The CNN COT retrieval framework was developed by Nataraja et al. (2022). It adapts a
1176 U-Net (Ronneberger et al., 2015) architecture and treats the retrieval of COT from radiance as a
1177 segmentation problem – probabilities of 36 COT classes (ranging from COT of 0 to 100) are
1178 returned as the final COT retrieved for a given cloud radiance field. It accounts for horizontal
1179 photon transport, which is neglected in traditional cloud retrieval algorithms; in other words, for
1180 the spatial context of cloudy pixels. It was trained on synthetic cloud fields generated by a Large
1181 Eddy Simulation (LES) model, which provides the ground truth of COT. Subsequently, Ear³T was
1182 used to calculate 3D-RT radiances at 600 nm for LES cloud fields to establish a mapping between

1183 radiance to COT. Only six LES cases were used to represent the variability of the cloud
1184 morphology. Each of these fields are 480x480 pixels across (spatial resolution of 100 m). These
1185 large fields were mapped onto thousands of 64x64 mini tiles with spatial resolution of 100 m as
1186 described in Nataraja et al., 2022. To keep the training data set small, mini tiles selectively sampled
1187 according to their mean COT and standard deviation. This ensured an even representation of the
1188 dynamic range of COT and its variability, which was termed homogenization of the training data
1189 set. Figure A1 shows a collection of samples from the training data as an illustration. All the
1190 mentioned simulation setup and techniques in data process are included in the App. 5 example
1191 code, which can be applied to the LES data (a different scene from the 6 scenes) distributed along
1192 with EaR³T.

1193

Formatted: Font: Bold

1198 Appendix C

Deleted: A

1200 C1. Cloud Detection/Identification

Deleted: A1

1201 Cloudy pixels are identified through a simple thresholding method based on the red, green,
1202 and blue channels of MODIS. When the radiance values of the red, green, and blue channels of a
1203 pixel are all greater than the corresponding median value, the pixel is considered as cloudy, as
1204 illustrated by the following equation

$$1205 \text{ If } \begin{cases} \text{Red} > \text{Median}(\text{Red}) \ \& \\ \text{Blue} > \text{Median}(\text{Blue}) \ \& \\ \text{Green} > \text{Median}(\text{Green}) \end{cases} \begin{cases} \text{Yes, cloudy} \\ \text{No, clear sky} \end{cases} \quad (\text{A1})$$

1206 Note that this only works for partially cloud-covered scenes, and may lead to false positives if
1207 there is brightness contrast from objects other than clouds. This method was specifically applied
1208 for the cases in this paper and should be changed as appropriate for future applications.

1210 C2. Two-Stream Approximation

Deleted: A2

1211 The two-stream approximation of the reflectance R is calculated using Eq. D2 from Chen
1212 et al. (2021), as follows:

$$1213 R = \frac{\tau + \alpha \cdot \left(\frac{2\mu}{(1-g) \cdot (1-\alpha)} \right)}{\tau + \left(\frac{2\mu}{(1-g) \cdot (1-\alpha)} \right)} \quad (\text{A2})$$

1214 where τ is the cloud optical thickness, α is the surface albedo, μ is the cosine of the solar zenith
1215 angle, and g is the asymmetry parameter. A value of 0.85 is assumed for g . The domain average
1216 of the solar zenith angle and surface albedo are calculated and used for estimating μ and α . Then,
1217 for a range of τ , we calculated the R and obtained the relationship of $R(\tau)$. For those cloudy pixels
1218 identified through A1, the inverse relationship of $\tau(R)$ is then used for estimating τ at any given
1219 R . Note that this approach does not take into account any cloud reflectance anisotropies.

1221 Appendix D

Deleted: B

1222 D1. Parallax Correction

Deleted: B1

1228 From the satellite's view, the clouds (especially high clouds) will be placed at inaccurate
 1229 locations on the surface, which have shifted from their actual locations due to the parallax effect.
 1230 We followed simply trigonometry to correct for it, as follows:

1231 Longitude correction (positive from west to east):

$$1232 \delta lon = \frac{(z_{cld} - z_{sfc}) \cdot \tan(\theta) \cdot \sin(\phi)}{\pi \cdot R_{Earth}} \times 180^\circ \quad (B1)$$

1233 Latitude correction (positive from south to north):

$$1234 \delta lat = \frac{(z_{cld} - z_{sfc}) \cdot \tan(\theta) \cdot \cos(\phi)}{\pi \cdot R_{Earth}} \times 180^\circ \quad (B2)$$

1235 where $(lon_{sat}, lat_{sat}, z_{sat})$ is the satellite location and θ and ϕ (0° at north, positive clockwise)
 1236 are the sensor viewing zenith and azimuth angles. z_{cld} and z_{sfc} are the cloud top height and the
 1237 surface height. R_{Earth} is the radius of the Earth. Figure A2 shows an illustration of parallax
 1238 correction for the [cloud field in the inset](#) in Figure 2.

1239

1240 **D2. Wind Correction**

1241 The wind correction aims at correcting the movement of clouds when advected by the wind
 1242 between two different satellites' overpasses.

1243 Longitude correction (positive from west to east):

$$1244 \delta lon = \frac{u \cdot \delta t}{\pi \cdot R_{Earth}} \times 180^\circ \quad (B3)$$

1245 Latitude correction (positive from south to north):

$$1246 \delta lat = \frac{v \cdot \delta t}{\pi \cdot R_{Earth}} \times 180^\circ \quad (B4)$$

1247 where u and v are the domain-averaged 10 m zonal and meridional wind speeds, and δt is the time
 1248 difference between two different satellites that fly on the same orbit. Figure A2 shows the cloud
 1249 location after applying the parallax (Appendix D1) and wind correction for the cloud field in the
 1250 [inset](#) from Figure 2.

1266 **Acknowledgement**

1267 The aircraft all-sky camera was radiometrically calibrated by the U.S. Naval Research Laboratory.
1268 We thank Jens Redemann for insightful discussions about Figure 9 (App. 3) about the apparent
1269 contradiction of the direction of the COT, reflectance, and transmittance biases.

1270
1271 **Data availability**

1272 For App. 1 and App. 2, the OCO-2 data were provided by the NASA Goddard Earth Sciences Data
1273 and Information Services Center (GES DISC, <https://oco2.gesdisc.eosdis.nasa.gov/data>) and the
1274 MODIS data were provided by the NASA Goddard Space Flight Center's Level-1 and Atmosphere
1275 Archive and Distribution System (LAADS, <https://ladsweb.modaps.eosdis.nasa.gov/archive>),
1276 which are all publicly available and can be downloaded by EaR³T through the application code.
1277 For App. 3, the AHI data were processed by Holz's (coauthor of this paper) team. The SPN-S data
1278 were provided by Schmidt and Norgren (coauthors of this paper). Both the AHI and SPN-S data
1279 are publicly available at NASA Airborne Science Data for Atmospheric Composition
1280 (<https://www-air.larc.nasa.gov/missions/camp2ex/index.html>). The AHI data and the SPN-S data
1281 for the flight track indicated in Figure 8 of the paper are distributed along with EaR³T for
1282 demonstration purpose. For App. 4, all sky camera imagery and CNN model are distributed along

1285 with EaR³T. EaR³T is publicly available and can be accessed and downloaded at
1286 <https://github.com/hong-chen/er3t> (or <https://doi.org/10.5281/zenodo.7374196> for v0.1.0 used in
1287 this paper; Chen and Schmidt, 2022).

1288

1289 **Author contributions**

1290 All the authors helped with editing the paper. HC developed the EaR³T package in Python
1291 including the application code, performed the analysis, and wrote the majority of the paper with
1292 input from the other authors. SS provided MCARaTS simulation wrapper code in Interactive Data
1293 Language (IDL); helped with the structure design of EaR³T; and helped with interpreting the
1294 results and writing the paper. SM helped with the OCO-2 data interpretation. VN trained and
1295 provided the CNN model. MN helped with the SPN-S instrument calibration and data processing.
1296 JG and GF helped with testing EaR³T and the LES data interpretation. RH provided the AHI data
1297 and helped with the data interpretation. HI helped with the implementation of MCARaTS into
1298 EaR³T.
