10

11 **Abstract.** Since its inception more than two decades ago proton-transfer-reaction mass-spectrometry (PTR-MS) has
12 established itself as a powerful technique for the measurements of volatile organic compounds (VOCs) providing high time
13 resolution, high sensitivity measurements without any sample pre-treatment. As this technology has matured and its application
14 become more widespread there is a growing need for accurate and traceable calibration to ensure measurement comparability.
15 As a result of the large number of VOCs detectable with PTR-MS it is impractical to have a calibration standard or standards
16 that cover all observable compounds. However, recent work has demonstrated that quantitative measurements of uncalibrated
17 compounds are possible provided that the transmission curve is sufficiently constrained. To enable this, a novel multi-
18 component gas reference material containing 20 compounds that spans the molecular weight range of 32 to 671 has been
19 developed. This development and the compositional evolution of this reference material are described along with an evaluation
20 of the accuracy and stability. This work demonstrates that for the majority of components the accuracy is < 5 % (most < 3 %;
21 < 10 % for hexamethylcyclotrisiloxane (D3-siloxane) and 1,2,4-trichlorobenzene (1,2,4-TCB)) with stabilities of > 2 years (>
22 1 year for acetonitrile, methanol and PFTBA).

23

24 1 Introduction

25 Proton-transfer-reaction mass-spectrometry (PTR-MS) is a technique that allows simultaneous measurements of multiple
26 volatile organic compounds (VOCs) in real-time (≤ 1 s) with high sensitivity (pmol mol^{-1}) and without any sample pre-
27 treatment (Lindinger et al., 1998; Hansel et al., 1999). For these reasons it is a very convenient measurement technique for a

28 wide range of applications. As a result, over the last two decades PTR-MS has developed to become an important and widely
29 applied method for VOC measurements that has resulted in major advances in the field of atmospheric sciences (De Gouw and
30 Warneke, 2007; Park et al., 2013; Yuan et al., 2017). It has also been applied in the medical and food and beverage fields for
31 the detection of VOCs to detect diseases (Beauchamp et al., 2013) and for characterising flavour and odour (Biasioli et al.,
32 2011).

33
34 Multiple manufacturers now produce and commercially sell PTR-MS instruments globally that differ in the production and
35 detection of ions including different types of mass spectrometer. Therefore, as its application becomes more widespread, and
36 more datasets are generated there is an increasing need for accurate calibration and measurement comparability. Additionally,
37 as part of the European funded Aerosols, Clouds and Trace Gases Infrastructure (ACTRIS) project (<https://www.actris.eu/>)
38 there is an interest to establish PTR-MS as a technique for long-term monitoring of VOCs, which emphasises the need for a
39 robust metrological infrastructure to control and assure the quality of data produced by monitoring stations performing these
40 measurements. However, the lack of traceable reference materials to calibrate PTR-MS instruments presents challenges in the
41 pursuit of obtaining comparable results and is an obstacle for long-term studies. Gas reference materials in high pressure
42 cylinders like those produced by national metrology institutes (NMIs) provide the necessary traceability to the international
43 system of units (SI) ensuring confidence that data is accurate and comparable. These primary reference materials (PRMs)
44 produced by the NMIs represent the highest point in the traceability chain and the accuracy and international comparability is
45 ensured through key comparisons organised within the Consultative Committee on Amount of Substance Gas Analysis
46 Working Group (CCQM-GAWG) and in regional comparisons organised within the Regional Metrology Organisations
47 (RMOs), e.g., EURAMET (Europe).

48
49 As a result of the large number of potential VOCs detectable with PTR-MS it is impractical to have a calibration standard or
50 standards that cover all observable compounds. However, since the conception of PTR-MS, there has been awareness for the
51 potential of this technique to provide quantitative measurements for compounds without the need for specific calibration
52 materials (Hansel et al., 1999). However, in practice, this potential cannot be fully exploited without reliable and applicable
53 methods to retrieve the mass-dependent transmission curve of the instrument. Recent work has demonstrated that a simple
54 reaction kinetics model can accurately predict the sensitivities of different PTR-MS instruments provided the transmission
55 curve was sufficiently constrained (Holzinger et al., 2019). This permits the quantification of measurements of uncalibrated
56 compounds with an accuracy of $\leq 30\%$. A prototype PRM to constrain the transmission curve was initially developed for the
57 PTR-MS intercomparison campaign at the CESAR observatory in the central Netherlands (Holzinger et al., 2019), this is NPL
58 PRM A574 reported in this work. Following this comparison exercise improvements to the composition were recommended
59 to include additional compounds in the mass-to-charge (m/Q) 150 – 400 range to provide a more robust retrieval of the mass
60 dependent transmission.

61

62 In this paper, the development and compositional evolution of an NPL PRM specific for constraining the PTR-MS transmission
63 curve is described, including an evaluation of the accuracy through comparisons validating the gravimetric preparation of
64 various different mixtures of similar composition and an assessment of their long-term stabilities.

65 **2 Experimental methods**

66 **2.1 Gravimetric preparation of primary reference materials**

67 The NPL primary reference materials (PRMs) were prepared at four distinct timepoints (September 2017, December-January
68 2018, August 2019 and August 2021) and the compositions evolved over this timeframe (Table 1) due to improvements in the
69 preparation and validation techniques (e.g., 1,2,4-trichlorobenzene; 1,2,4-TCB) or due to requests from the PTRMS
70 community for inclusion of new components (e.g., dimethyl sulphide; DMS). All the NPL PRMs were prepared gravimetrically
71 in accordance with ISO 6142-1:2015 (ISO, 2015) from pure components. All pure components were purity analysed in
72 accordance with ISO 19229 (ISO, 2019). Table 1 provides the sources and purities for each component and shows that all
73 chemicals with the exception of PFTBA were $\geq 98\%$ pure. All components were liquids at room temperature and pressure,
74 with the exception of propane (gas) and hexamethylcyclotrisiloxane (D3-siloxane; solid). As a solid, D3-siloxane needed to
75 be dissolved into a solvent to enable its addition to the cylinder (see details in the Supporting Information).

76
77 All NPL PRMs were prepared in 10 L aluminium cylinders (Luxfer) with a proprietary passivation treatment (Spectraseal™,
78 BOC) and BS341 no. 15 outlet diaphragm valves (Ceodeux). Cylinders were evacuated using an oil free pump (Scrollvac
79 SC15D, Leybold Vacuum) and turbo molecular pump with magnetic bearing (Turbovac 340M, Leybold Vacuum) to a pressure
80 of $< 3 \times 10^{-7}$ mbar. Individual compounds were added to the evacuated cylinder via a transfer vessel (capped $1/8$ " diameter
81 tube, with a nominal volume of 1 mL, Swagelok, electro-polished stainless steel). The transfer vessel was weighed against a
82 tare vessel matched for size and shape before and after each addition into the evacuated cylinder (Mettler-Toledo XP2004S).
83 The ultra-high purity nitrogen balance gas (BIP+, Air Products) was added via direct addition to the cylinder, through purged
84 $1/16$ " tubing (Swagelok, electro-polished stainless steel). For the vast majority of compounds, they were initially produced as
85 binary parent mixtures at amount fractions $> 10 \mu\text{mol mol}^{-1}$ (typically at nominally $50 \mu\text{mol mol}^{-1}$) though some were produced
86 as ternary or quaternary mixtures containing two or three compounds together in the same parent mixture. A full breakdown
87 of the 50 parent mixtures used for each of the six NPL PRMs are shown in Table 2. Aliquots of each of these parent mixtures
88 were added by direct addition to an evacuated cylinder to produce a final mixture containing all 16 to 20 VOCs at nominal 1
89 $\mu\text{mol mol}^{-1}$ in a balance of nitrogen.

Table 1. Overview of composition (name, formula, CAS# and the monoisotopic molecular ion (MH⁺) formed following protonation in H₃O⁺ mode) of the PTRMS transfer curve reference material including the analytical technique used to validate, sources and purities of the pure chemicals and the key comparisons through which the traceability to the international community is derived.

Compound ^a	Formula	CAS #	MH ⁺	Traceability (Reference, if applicable)	Validation technique	Source	Purity (%)

92 2.2 Analytical methods

93 To perform the analytical validation a method was developed on a gas chromatograph (GC; Agilent Technologies 7890)
94 instrument equipped with both a flame ionisation detector (FID) and mass spectrometer (Agilent 5975; GC-FID/MS system).
95 Samples were introduced using a 6 port 2 position valve (VICI) and a fixed sampling loop (1 mL). The column effluent was
96 split to both detectors simultaneously through the use of a detector splitter plate (Agilent Technologies). Separation was
97 achieved for all components using a DB-624 column (J&W; 75m × 0.53 mm, df = 3 μm), although 3-carene and 1,2,4-TMB
98 were not baseline separated. The carrier gas was helium and the flow was held constant at 5 mL min⁻¹, with a temperature
99 program starting at 30 °C held for 10 minutes, ramped at 10 °C min⁻¹ to 120 °C and held for 15 minutes before a final ramp of
100 50 °C min⁻¹ was applied to a final temperature of 200 °C, which was held for a further 10 minutes. The total run time was 46
101 minutes.

102

103 Low FID responses for methanol and acetaldehyde presented some challenges for validation work as the observed peaks were
104 too small to achieve useable results due to poor reproducibility. As a result, another analytical method was developed on a
105 second GC-FID instrument without an MS (Scion 456; Cryo-GC-FID system) that had a pre-concentration loop packed with
106 glass beads and cooled with liquid nitrogen that enabled trapping of larger volume samples yielding larger peaks and improved
107 repeatability for these three compounds. Separation was achieved using a Rtx-624 (Restek; 105m × 0.32 mm, df = 1.8 μm).
108 The carrier gas was hydrogen and the flow was held constant at 1 mL min⁻¹, with a temperature program starting at 30 °C held
109 for 5 minutes, ramped at 25 °C min⁻¹ to 200 °C with a final hold of 25 minutes. The total run time was 42 minutes.

110

111 Figure 1 shows the chromatograms obtained from both instruments (cryo-GC-FID, blue; GC-MS/FID, red) and demonstrates
112 that all compounds, with the exception of 1,2,4-trimethyl benzene (1,2,4-TMB) and 3-carene, and acetone and dimethyl sulfide
113 (DMS), were baseline separated. The chromatogram in Fig. 1 shows a valley between the 1,2,4-TMB and 3-carene peaks and
114 between the acetone and DMS peaks that provides sufficient separation to obtain robust and repeatable peak areas for all four
115 compounds.

116

117 **Figure 1.** Chromatogram of NPL PRM 2819 showing separation of compounds in the GC-FID/MS (thin red trace) and cryo-
118 GC-FID (thick blue trace).
119

120

121 2.3 Stability assessment

122 Stability of all six NPL PRMs were assessed by tracking the ratios of the FID responses of each component relative to an
123 internal reference that was present in every mixture and which is known to be stable (Rhoderick, 2010; Rhoderick and Lin,
124 2013; Worton et al., 2022). Propane was originally included as an internal tracer to monitor stability but as the PTR-MS in
125 H_3O^+ mode cannot detect this compound it was replaced by benzene. Benzene is a good internal tracer with stability of > 2
126 years that has been well demonstrated relative to propane and hexane for this cylinder type at $5 \mu\text{mol mol}^{-1}$ with an uncertainty
127 of 0.5 % (Rhoderick et al., 2019). A similar performance would be expected at $1 \mu\text{mol mol}^{-1}$ and is demonstrated in this work
128 albeit with an uncertainty of 1 % (Fig. S2, Supporting Information).

129

130 All the measurements used for the stability analysis were collected on the same GC-FID/MS instrument with the exception of
131 methanol and acetaldehyde (Cryo-GC-FID). Both instruments remained unchanged throughout the entire time-period of the
132 measurements, which spanned more than 4 years. The observed responses for each compound were corrected for differences
133 in the gravimetric amount fraction and ratioed against the internal reference compound benzene, that was present in every
134 mixture. The uncertainties in the observed ratios included uncertainties for the gravimetric preparation and the repeatability of

135 the analyses. The combined standard uncertainties were multiplied by a coverage factor of 2 ($k=2$) providing a coverage
136 probability of 95 %. The observed ratios were normalised to the average response of all data for that compound to enable
137 comparisons between compounds with different FID responses. For this analysis all the data for all six NPL PRMs were
138 considered together to enable an understanding of stability across a longer time period than would be possible for a single
139 PRM. Least squares fit straight-line regressions were modelled to the temporal evolution of the data to determine if there was
140 any statistically significant change in amount fraction of any of the compounds in the NPL PRMs. The slopes from these
141 regression analyses were evaluated with an analysis of variance (ANOVA) test using the ‘StatsLinearRegression’ function in
142 IGOR pro 8.04 (Wavemetrics) (Zar, 1999; Snedecor and Cochran, 1989) to determine whether they were significantly different
143 to zero using an F -test, i.e., no drift in amount fraction during the measurement period ($F < F_c$).

144

145 2.4 Validation approach

146 All 5 NPL PRMs (A574, A578, A638, A643, D961492) were validated against NPL PRM 2819 with the exception of PFTBA
147 and toluene that were only present in the most recent NPL PRM (D961492). NPL PRM 2819 was used as the reference for all
148 the validations because the parents used for the preparation of this mixture were deliberately different from all other mixtures
149 with the explicit goal of enabling the most robust validation. All compounds were analysed on the GC-FID/MS system, with
150 the exception of methanol and acetaldehyde (Cryo-GC-FID). Toluene was validated by comparison against an existing NPL
151 PRM containing BTEX (benzene, toluene, *m*-xylene, *p*-xylene and *o*-xylene) components. PFTBA was validated against the
152 gravimetric data used to make two independent certified reference materials. The majority of the validation work took place
153 between September and December 2020 with one in 2019 and 2022, respectively, and three in 2021 (see Table S1, Supporting
154 Information). As such there is an influence of stability on the validation data as the PTRMS NPL PRMs differed in age at the
155 time of validation.

156

157 Each comparison was conducted by running the NPL PRMs (A574, A578, A638, A643 and D961492) against NPL PRM 2819
158 in a repeating alternating pattern, $(ABA)_n$ where A represents NPL PRM 2819 and B one of the other PRMs (j) and with the
159 number of repeats ranging between 3 and 5 ($n = 3 - 5$). The ratio in response was determined by bracketing between the nearest
160 neighbours and the average ratio was calculated for each compound based on the number of repeats along with the associated
161 standard deviation. The assigned analytical value for compound i in NPL PRM j ($x_{u,i,j}$) was calculated by multiplying the
162 average ratio by the gravimetric amount fraction ($x_{s,i}$) of compound i in NPL PRM 2819. The relative difference (Δx) between
163 the assigned analytical value and the gravimetric value of compound i in NPL PRM j was calculated from:

164

$$165 \quad \Delta x = \frac{(x_{u,i,j} - x_{s,i})}{x_{s,i}} \times 100$$

Eq. 1

166

167 The uncertainty in the relative difference combined the standard uncertainty in the repeatability in the analysis with the
168 gravimetric uncertainty. The combined standard uncertainty was multiplied by a coverage factor of 2 ($k=2$) providing a
169 coverage probability of 95 %.

170 **3 Results**

171 **3.1 Composition**

172 The PTR-MS transfer curve reference material contains 20 different VOCs that span a wide range of molecular masses from
173 32 to 671 and a range of functional group classes including alcohol, aldehyde, ketone, alkene, aromatic, halocarbon and
174 siloxane (Table 2). With PTR-MS, most are entirely detected at their protonated mass, as well as a few compounds that partially
175 fragment during protonation (e.g. monoterpenes, siloxanes, and isoprene). The compounds were chosen by considering the
176 needs of the PTR-MS user community to cover the full range of mass-to-charge ratios (m/Q) encountered, their low
177 fragmentation following proton transfer and because many are of relevance in atmospheric measurements, which was the initial
178 intended target end user group. Other compounds were included as a consequence of the preparation method, that is the case
179 of *n*-hexane included as diluent for D3-siloxane or propane which was present in one of the premixtures and was originally
180 included as an internal tracer to monitor stability. The composition evolved over time, as shown in Table 2, with DMS, 1,2,4-
181 TCB, D3-siloxane, toluene and PFTBA being added at different times, and propane being removed in the final iteration. For
182 D4-siloxane there was a preparation error, and it was not added to either NPL PRM A638 or A643.

183
184 An amount fraction of nominally $1 \mu\text{mol mol}^{-1}$ in a balance gas of nitrogen was selected as a compromise between preparation
185 complexity and mixture stability. This amount fraction enabled many components to be prepared from parent mixtures of
186 higher amount fraction ($\geq 10 \mu\text{mol mol}^{-1}$), which substantially simplifies the preparation process. This amount fraction also
187 provided a reasonable starting point for stability of the wide range of function groups present in the mixture some of which are
188 known to have more limited stability at lower abundances fractions (nmol mol^{-1}) (Allen et al., 2018).

189 **3.2 Traceability to the International System of Units (SI)**

190 Traceability of the primary realisations to the international community through CCQM key comparisons or regional
191 EURAMET comparisons provides confidence in the accuracy of the amount fractions for all components. Table 1 shows which
192 comparisons underpin the traceability for each of the different components. All the components are underpinned by at least
193 one CCQM or EURAMET comparison with the exception of 1,2,4-TFB, 1,2,4-TCB and PFTBA, for which there are currently
194 no existing relevant comparisons.

195 3.3 Hierarchies

196 Table 2 shows all the parent mixtures and their preparation dates used for the preparation of all 6 NPL PRMs. In total, 50
197 different parent mixtures were used to produce the 6 NPL PRMs (A574, A578, A638, A643, 2819, D961492). In general,
198 parent mixtures were similar for A574, A578, A638 and A638 but were different to 2819 and D961492 providing independence
199 and thus confidence in the validation work and thus the preparations. There were a few exceptions. For *m*-xylene the parent
200 used for A638 and A643 were the same as D961492 but different to A574, A578 and D961492. For 1,2,4-TMB only two
201 parent mixtures were used one for A574, A578 and D961492 and another for A638, A643 and 2819. For 3-carene only two
202 parents were used one for A574 and A578 and another for A638, A643, 2819 and D961492. For D3-siloxane three parents
203 were used, one for A638 and 2819, another for A643 and another for D961492.

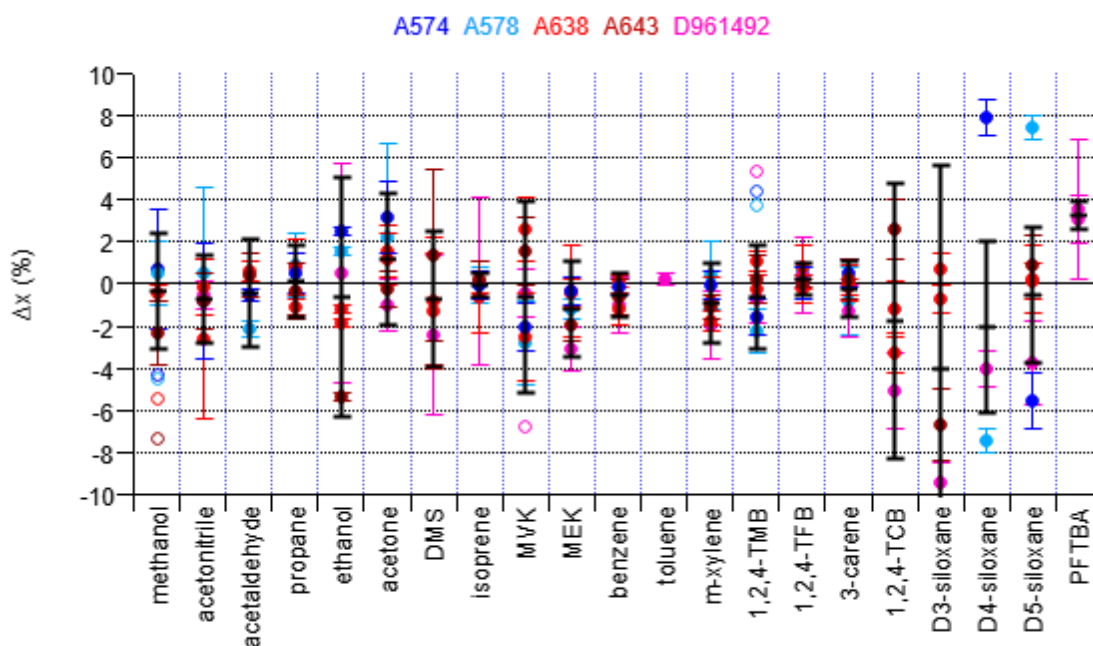

204 3.4 Validation

205 Figure 2 shows the relative differences (Δx) determined from Eq. 1 for all compounds using all the validation data obtained
206 from the 13 comparisons outlined in Table S1 (Supporting Information). All the data shown in Fig. 2 is the FID data from the
207 GC-MS/FID instrument with the exception of acetonitrile (MS data from the GC-MS/FID instrument), methanol and
208 acetaldehyde (FID data from the cryo-GC-FID instrument). The MS data is used for acetonitrile because the FID data shows
209 more variability likely as a result of the small FID peak size. This variability is not observed in the MS data providing better
210 precision (Fig. S1, Supporting Information).

211
212 In general, the data from Fig. 2 could be split into three groups. The first group consisted of propane, isoprene, benzene,
213 toluene, 3-carene, methanol, acetonitrile, acetaldehyde, *m*-xylene, 1,2,4-TMB, MEK where the spread in the validation data is
214 within 3 % and these represent components where NPL had substantial prior experience. The second group is acetone, DMS,
215 MVK and PFTBA where the spread in the validation data is within 5 % and these are relatively new components where
216 capabilities were developed more recently. Recognising the challenges in preparing PRMs containing siloxanes as a result of
217 their low vapour pressures and observing the recent improvements in preparation since 2019, the D4-siloxane and D5-siloxanes
218 can also be categorised as group 2 after excluding the earliest parent preparations used for A574 and A578 in 2017, which are
219 inconsistent with more recent work as part of the EURAMET 1305 Siloxanes comparison (Van Der Veen et al., 2022). The
220 final group is comprised of D3-siloxane and 1,2,4-TCB where the spread in validation data is within 10 % and these compounds
221 represent those which the most challenging to prepare as a result of their low vapour pressures. There is an observable bias of
222 about 8 % between two groups of mixtures; one group is A638 and 2819 and the other is A643, D961492. This reflects
223 differences between the parent mixtures (2586, 2693 and 3134) that resulted from the challenges in preparation. Ethanol also
224 sits with this group in part due to the small size of the peak observed in the GC-MS/FID instrument and because of what looks
225 like an outlier (A643), suggesting some potential losses during preparation that were unique to this one NPL PRM.

226 **Figure 2.** Relative difference (Δx) using the FID data (except acetonitrile, which uses the MS data) for all components in the
227 different primary reference materials (A574, A578, A638, A643 and D961492) relative to primary reference material 2819
228 (solid symbols). The solid black line represents the average of these validations with the error bar representing the associated
229 expanded uncertainty (2σ). For D4- and D5-siloxane the averages do not include the validations from A574 or A578. Methanol
230 and acetaldehyde data are from the cryo-GC-FID instrument while all others are from the GC-FID/MS instrument. Open
231 symbols represent the original data before correcting for biases observed in three of the parent mixtures (A410, 5 % low for
232 methanol; 3070, 6.3 % low for MVK and D711530 6 % low for 1,2,4-TMB). PFTBA and toluene were only included in the
233 most recently prepared PRM (D961492) and are not present in 2819. Their validation is described in the text. Supporting
234 validation data from all the MS and FID measurements is shown in Fig. S1 (Supporting Information).
235

236
237

238 All the FID and supporting MS data for all compounds are shown in Fig. S1 (Supporting Information). No MS data was
239 available for toluene, 1,2,4-TCB or PFTBA because the relevant single m/Q ions had not been included in the MS single ion
240 monitoring method at the time of analysis and methanol where the MS signal was too small to provide a reliable response.
241 Figure S1 shows very good agreement between the FID and MS validation with all components agreeing within the
242 uncertainties providing confidence in the validation results.
243

244 In addition to the observed bias in parent mixtures for D3-siloxane three other parent mixtures were also discovered to be
245 biased after re-analysis. The observed differences have been corrected for in Fig. 2 and Fig. S1 (Supporting Information). For
246 methanol, one parent (A410) was confirmed to be 5.0 % high relative to the other parents (A463, A540 and A602) For MVK,
247 one parent (3070) was confirmed to be 6.3 % low relative to the other parents (2064 and 2088). For 1,2,4-TMB, one parent
248 D711530 was confirmed to be 6.0 % low relative to D442684 and other in-house standards of 1,2,4-TMB not used in this work
249 but used to prepare 30 component ozone precursor mixtures at NPL (Grenfell et al., 2010).

250 3.5 Stability

251 Figure 3 shows the stability data for four selected compounds; methanol, isoprene, D3-siloxane and PFTBA. These were
252 selected as representative examples of the different observed stability behaviours although the stability data plots
253 corresponding to all compounds are shown in Fig. S2 (Supporting Information). The trendlines from the least squares fit
254 straight-line regressions shown in Fig. 3 and Fig. S2 (Supporting Information) were used to determine the annual drift rates
255 shown in Table 3 and Fig. 4. From the ANOVA test there are statistically significant trends ($F > F_c$) for 10 of the compounds
256 (methanol, acetonitrile, acetaldehyde, ethanol, acetone, DMS, isoprene, MVK, benzene, D3-siloxane) but these trends are
257 small ($< 2\% \text{ yr}^{-1}$) except for methanol, acetonitrile and PFTBA.

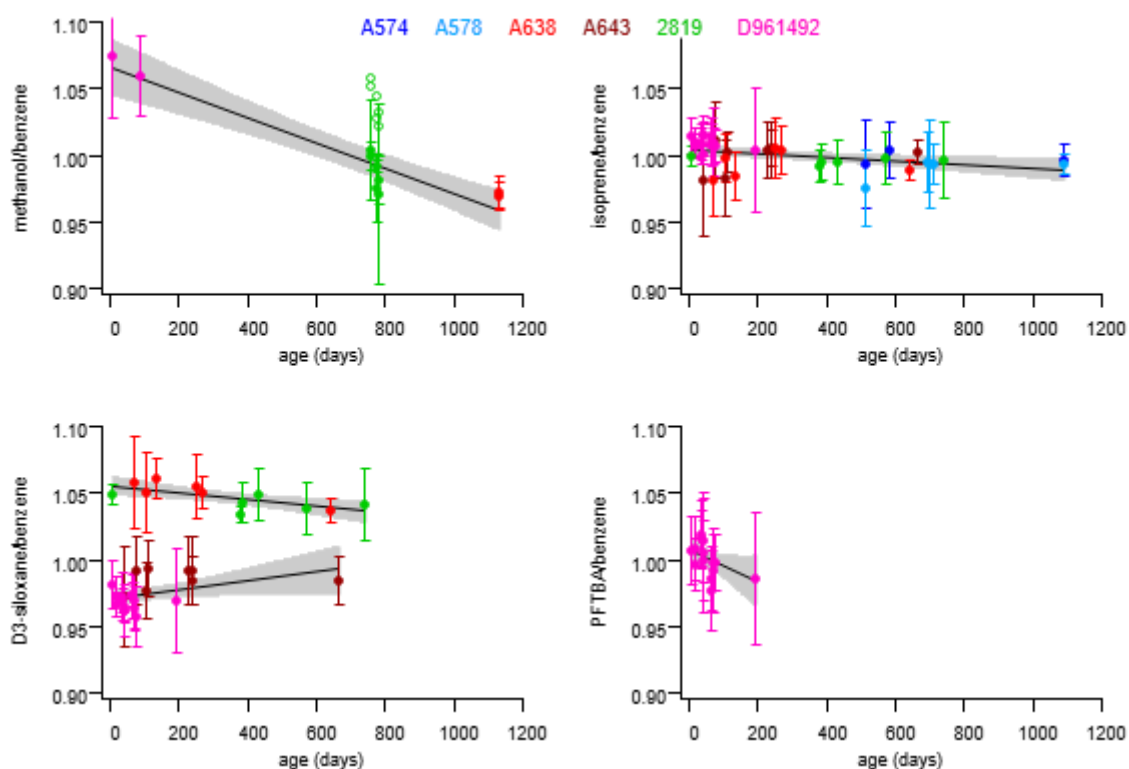

258
259 Methanol and acetaldehyde were the only two components that were measured on the cryo-GC-FID and hence the datasets are
260 more limited. A result is that there is no overlap between the three NPL PRMs so any systematic differences between them
261 may result in an artificial bias, which may exacerbate any stability trend. More work is needed to confirm this. The stability
262 data for D3-siloxane reflects the observed validation bias and shows two clear trends; one for A638 and 2819 and the other for
263 A643 and D961492. For the regression analysis and drift calculations these have been treated independently (Table 3).

264
265 All compounds, with the exceptions of methanol, acetonitrile and PFTBA, show trends similar to isoprene with good stability
266 and annual drift rates of $< 3\% \text{ yr}^{-1}$ (Table 3). For acetonitrile the large spread in validation data (FID data; Fig. S1, Supporting
267 Information) leads to a noisy stability dataset that may play a role in the larger observed drift rate or this component maybe
268 less stable. Additional work is needed to confirm. As PFTBA was only included in the last NPL PRM (D961492) the stability
269 data only represents about half a year and extrapolating the current trend to 1 and 2 years results in a drift rate that is not
270 accurate as interpolation of the data would suggest no statistical change in amount fraction and minimal drift. More data is
271 needed to confirm the longer-term stability behaviour of PFTBA.

272
273
274
275

276 **Figure 3.** Stability of normalised response with time for four selected compounds relative to benzene, methanol (top left),
277 isoprene (top right), D3-siloxane (bottom left) and PFTBA (bottom right) for all six NPL PRMs (solid symbols). The open
278 symbols (methanol; top left) show the original data before being corrected for an observed 5.0 % bias in the parent mixture
279 (A410). The best fit curves from least squares straight line regression analyses are shown (solid black line) along with the 95
280 % confidence interval of the fits (shaded area). The slope, intercept and F-statistic data from the regression analyses are shown
281 in Table 3. Stability plots for all compounds are shown in Fig. S2 (Supporting Information).
282

283

284

285

286 Given the age differences between the different PRMs at the time of validation (233 – 709 days; Table S1, Supporting
287 Information) it is not possible to deconvolute the contributions of stability and preparation to the observed validation
288 differences. However, Fig. 4 shows that for the majority of compounds there is good agreement between the observed average
289 validation data and the calculated drift for over 1 – 2 years, with the exception of methanol, acetonitrile and PFTBA, which
290 differ for the reasons discussed previously. These observations are consistent with the age differences of the different PRMs
291 at the time of validation indicating that stability was likely the major driver between the observed validation differences.

292

293 **Table 3.** Summary of the results of the least squares straight-line regression analysis for all stability data shown in Figures 3
 294 and S2 (Supporting Information). Results are shown for the slope ($\pm 2\sigma$), intercept ($\pm 2\sigma$), ANOVA test statistics (F and Fc)
 295 used to evaluate the presence of a statistically significant trend ($F > F_c$), the calculated annual drift ($\pm 2\sigma$) determined from the
 296 linear fit and the average of the validation data ($\pm 2\sigma$), also shown in Figure 2.

297

compound	slope ($\times 10^{-5}$)	intercept	F	F _c	Drift (%/yr)	Avg valid. (%)

298 ^aThe GC-FID data for methanol and acetaldehyde was too small to be quantified so this data is from the cryo-GC-FID data and is limited. ^bBenzene stability
 299 was determined relative to isoprene. ^cThere was a clear bias between several of the PRMs caused by differences in the parent mixtures used so the trends were
 300 fitted to the two obvious groupings. ^dData from A574 and A578 was excluded from the regression analysis. ^eToluene and PFTBA were only included in the
 301 most recent NPL PRM so the assessment of stability is limited in its duration to only 200 days.

302

303 **Figure 4.** Comparison of 1-year (filled grey squares) and 2-year (open grey squares) drift rates, calculated from the data in
304 Table 3, with the average validation data (black bars) taken from Fig. 2. For D3-siloxane there are two datapoints for the drift
305 correspond to the two regressions shown in Table 3. The error bars represent the associated expanded uncertainties,
306 representing the 95 % confidence limit.
307

308

309 4 Conclusions

310 In this work the development of a new primary reference material (PRMs) for constraining the mass dependent transmission
311 curve of PTR-MS instruments has been described along with an evaluation of their validation and stability. Six of these PRMs
312 have been prepared to date from a suite of 50 parent mixtures. In general, there is evidence of very good agreement for the
313 majority of components that supports the robustness of the preparation and 2 years of stability. Challenges were observed in
314 preparation for the least volatile compounds especially for D3-siloxane due to it being a solid at room temperature and pressure.
315 More work is needed to better describe the long-term stability of methanol, acetonitrile and PFTBA. This work highlighted
316 several challenges in analysis that could be resolved by the development of a new analytical method utilised a single instrument
317 equipped with both a preconcentration trap and dual detector setup (MS and FID).

318

319 Future work to improve the uncertainty of individual components that have the greatest influence on the transmission curve fit
320 would have the biggest influence on the accuracy and repeatability of the transfer curve fit thus maximising the impact of
321 future improvements for the PTRMS user community. For PTRMS instruments that utilise time of flight mass spectrometers
322 the focus would be on improving the uncertainty of the largest molecular weight components specifically the D3-, D4-, D5-
323 siloxanes and 1,2,4-TCB, which represent the greatest challenges in preparation due to their low vapour pressures.

324 **Data availability**

325 All data used to produce the figures in this paper are available on request.

326 **Competing interests**

327 The authors declare that they have no conflict of interest.

328 **Author contributions**

329 DRW and RH conceptualized the work. DRW processed the data, produced the figures and tables and wrote the paper. SM
330 developed novel methods for the preparation of primary and certified reference materials, planned and prepared all reference
331 materials, conducted all the validation and stability data collection and contributed to the writing of the paper. KOD contributed
332 to the preparation of reference materials, reprocessed some of the stability data and worked with SM to prepare the certified
333 reference materials. RH provided inputs to define the composition of the PTR-MS reference material and reviewed the paper.

334 **Financial support**

335 NPL acknowledges funding from the Department of Business Energy and Industrial Strategy (BEIS) National Measurement
336 System. RH acknowledges funding from the EMPIR programme (19ENV06 MetClimVOC), co-financed by the Participating
337 States and from the European Union's Horizon 2020 research and innovation programme, and from the European Union's
338 Horizon 2020 research and innovation programme (ACTRIS-2) under grant agreement no. 654109.
