13 Abstract

14 Values of undercatch-corrected liquid-equivalent snowfall rate (S) at a ground site and
15 microwave reflectivity (Z) retrieved using an airborne W-band radar were acquired during
16 overflights. The temperature at the ground site was between -6 and -15 °C. At flight level, within
17 clouds containing ice and supercooled liquid water, the temperature was approximately 7 °C
18 colder. Additionally, airborne measurements of snow particle imagery were acquired. The
19 images demonstrate that most of the snow particles were rimed, at least a flight level. A
20 relatively small set of S/Z pairs (4) are available from the overflights. Important distinctions
21 between these measurements and those of Pokharel and Vali (2011), who also reported W-band
22 S/Z pairs for rimed snow particles, are 1) the fewer number of S/Z pairs, 2) the method used to
23 acquire S , and 3) the altitude, relative to ground, of the Z retrievals. This analysis indicates that
24 the S/Z relationship reported in Pokharel and Vali (2011) yields an S , in scenarios with snowfall
25 produced by riming, that is substantially larger than that derived using an S/Z relationship
26 developed for unrimed snow particles.

27

28 1 - Introduction

29 Improvement of methods used to measure snowfall and rainfall are an ongoing focus of
30 meteorological research. The various methods are ground-based instruments that evaluate the
31 mass of precipitation that falls into or onto a collector (precipitation gauges) (Brock and
32 Richardson 2001), ground-based radars (Wilson and Brandes 1979), and airborne and space-
33 borne radars (Matrosov 2007; Kulie and Bennartz 2009; Geerts et al. 2010; Skofronick-Jackson
34 et al. 2017). An objective of these approaches, whether used to make observations independent
35 of other methods (e.g., Kulie and Bennartz 2009), or as a component of multiple observations
36 (e.g., Cocks et al. 2016), is estimation of precipitation rate and accumulation.

37 Many studies have investigated using radar for evaluating rainfall (for a review see
38 Wilson and Brandes 1979). There are two approaches. The first is research, both observational
39 and computational, that probes the relationship between rainfall rate (R) and radar-measured
40 values of range-corrected backscattered microwave power. The latter is commonly reported as an
41 equivalent radar reflectivity factor (Z_e). The second is operational in the sense that precipitation
42 gauges are used to calibrate measurements acquired using weather surveillance radars.
43 Complications associated with converting Z_e to R, or converting a radar reflectivity factor¹ (Z) to
44 R, can be grouped in four categories: 1) Inaccuracy in quantification of Z, 2) variation of the
45 R/Z relationship stemming from precipitation processes (e.g., coalescence and break up), 3)
46 difference between the volume of a radar range gate versus the much smaller volume of
47 atmosphere sampled as precipitation falls to a gauge, and 4) vertical displacement between a
48 radar range gate and a calibrating gauge, especially at far ranges.

¹ Radars are calibrated to report Z_e (Smith 1984). Herein, radar reflectivities are reported as $Z = Z_e$ and as $\text{dBZ} = 10\log_{10}(Z_e)$.

49 For situations with snowfall, methods employing either gauge or radar are associated
50 with complications beyond that incurred in rainfall (Matrosov 2007; Martinaitis et al. 2015;
51 Cocks et al. 2016). Problems associated with gauge measurements are wind-induced snow
52 particle undercatch, gauge capping, delayed registration, and blowing snow aliasing as snowfall.
53 Moreover, in a situation with snow particles most abundant within a radar range gate, compared
54 to rain drops, and where a measurement of Z is used to infer R via a R/Z relationship, the
55 resultant precipitation rate will likely be inaccurate. This is because hydrometeor shape, density,
56 and dielectric properties are all variable for snow particles while relatively invariant for rain
57 drops. Additionally, a snow particle's terminal fall speed varies with size (as is the case for
58 drops) and with particle shape and particle density. Going forward, we refer to the latter two
59 properties as shape and density.

60 The goals of this paper are as follows: 1) to describe measurements of undercatch-
61 corrected liquid-equivalent snowfall rate (S , mm h^{-1}) and how these were paired with W-band
62 measurements of reflectivity (Z , $\text{mm}^6 \text{m}^{-3}$); 2) to contrast the S/Z pairs against S/Z relationships
63 commonly applied in radar retrievals of S ; and 3) to investigate why the S/Z pairs deviate from
64 predictions of some S/Z relationships.

65 In calculations of paired values of S and Z , density is an important parameter. Density is
66 commonly estimated using empirical data (e.g., Pokharel and Vali 2011, [PV11]). For graupel, a
67 snow particle that grows via collection of supercooled cloud droplets in a process commonly
68 referred to as riming, paired observations of particle mass and particle size have been used to
69 estimate density. There is considerable uncertainty in this approach. Based on data collected at
70 two northwestern US surface sites (Zikmunda and Vali 1972; Locatelli and Hobbs 1974), density
71 values differ by at least a factor of two at particle sizes smaller than $2000 \mu\text{m}$ (PV11; their Fig.

72 4). Given that the density of rime ice varies with droplet impact speed, droplet size, and
73 temperature (Macklin 1962), it is not surprising that the density-size relationships analyzed by
74 PV11 are so varied.

75 The following introductory paragraphs overview W-band S/Z relationships being applied
76 in instances of snowfall where mass is acquired by vapor deposition (crystal), by collection of
77 crystals (aggregate), and by riming (rimed crystal and graupel). Henceforth, the latter two snow
78 particle types are collectively referred to as rimed snow particles.

79 In a computational study, Hiley et al. (2011) considered a variety of snow particle types
80 (column, plate, bullet rosette, sector plate, dendrite, and aggregate), employed a parameterized
81 ice particle size distribution (PSD) function (Field et al. 2005), accounted for a range of
82 temperature (-5 to -15 °C) via the Field et al. parameterization, and developed a range of S/Z
83 relationships for snow particles. Except for the aggregates, the modeled particle types were
84 vapor-grown crystals. Hiley et al.'s upper- and lower-limit relationships are $S = 0.21 \cdot Z^{0.77}$ and S
85 $= 0.024 \cdot Z^{0.91}$. Matrosov (2007) developed an S/Z relationship for aggregates. In that work,
86 parameterized PSDs from Braham (1990) were employed, and a range of particle aspect ratios
87 were factored into the calculations. For aggregates, the S/Z relationship is $S = 0.056 \cdot Z^{1.25}$
88 (Matrosov 2007). It should be noted that Hiley et al. (2011) and Matrosov (2007) employed
89 similar, but not identical, computational methods. Kulie and Bennartz (2009) developed an S/Z
90 relationship for what they referred to as a "snow particle" type. The wavelength-dependent
91 density derived by Surussavadee and Staelin (2007) (200 kg m^{-3} at $\lambda = 3.2 \text{ mm}$) was adopted, the
92 snow particles were modeled as spheres, and the Field et al. parameterization was applied. The
93 S/Z relationship developed for this particle type is $S = 0.52 \cdot Z^{0.83}$ (Surussavadee and Staelin 2007;
94 Kulie and Bennartz 2009; henceforth SSKB). Variance in the calculations discussed in this

95 paragraph originate from changes in density, shape, fall speed, PSD, and particle size as these
96 changes are propagated through the cloud-microphysical and microwave-scattering calculations.

97 In a hybrid approach (computational and an analysis of airborne observations), PV11
98 concluded that most of the snow particles they imaged were rimed snow particles. Values of S
99 were calculated using a density-size function (ρ_1 , discussed below), a fall speed-size function, a
100 measured PSD and measured particle images, and a determination of particle volumes. It was
101 assumed that a prolate spheroid approximated particle shape and this was the basis for
102 determining a particle's sphere-equivalent volume and the particle's sphere-equivalent size. The
103 sphere-equivalent size was applied in the two functions. Values of Z were calculated using a
104 measured PSD, sphere-equivalent sizes, the ρ_1 function, and Mie Theory. PV11 presented
105 calculations of Z , obtained using two density-size relationships (their Eqs. 1 and 2) and compared
106 their calculated reflectivities to measurements of Z from a W-band radar. That led to their
107 conclusion that "...the lower density assumption...yielded closer correspondence to observed
108 reflectivities." Their recommendation for S as a function of measured Z - hereafter the $S(\rho_1)/Z$
109 best-fit line - is $S = 0.39 \cdot Z^{0.58}$. Values of Z that were paired with the calculated values of S (i.e.,
110 the S/Z pairs from PV11 that we present in Sect. 4), and that were used to determine the $S(\rho_1)/Z$
111 best-fit line, came from the WCR. In addition to variance in their values of S , coming from a
112 dependence on density, PV11 state that a value of S derived via their best-fit line is uncertain by
113 a factor-of-ten. That uncertainty is evident in the variance of S/Z data pairs about the $S(\rho_1)/Z$ line
114 in Fig. 11 of PV11. Those investigators, and Geerts et al. (2010), attributed the variance to use of
115 two-dimensional snow particle images in calculations of S and to actual variations of density,
116 shape, and particle size not accounted for in the calculations.

117 Also relevant are S/Z relationships reported by Falconi et al. (2018; their Table 2). These
118 were developed using measurements from a video disdrometer, weighing precipitation gauge,
119 microwave radiometer, and a vertically-pointing W-band radar. All these systems were operated
120 at the ground. The data set was stratified into intervals of lightly-rimed, moderately-rimed, and
121 heavily-rimed snow. A proxy for snow particle riming - radiometer measurements of liquid water
122 path – was the basis for the stratifications (von Lerber et al. 2017). The S/Z relationships are $S =$
123 $0.10 \cdot Z^{1.0}$ (lightly-rimed), $S = 0.079 \cdot Z^{1.3}$ (moderately-rimed), and $S = 0.060 \cdot Z^{1.4}$ (heavily-rimed).

124 Our focus is on surface measurements of S and on pairing of those measurements with
125 airborne measurements of Z. We also analyze airborne measurements of snow particle imagery.
126 The latter demonstrates that the particles observed at flight level were rimed. These
127 measurements are the basis for our assertion that our data set is relevant to ongoing
128 investigations of using Z to evaluate S in situations where precipitation is produced by riming.

129 Section 2 describes the setting of our study, the instruments we deployed, and recordings
130 we obtained using two data acquisition systems. One of the data systems was operated at a
131 ground site and the other on an aircraft. Section 3 is an analysis of the recordings; this section
132 also considers recordings from two additional, but ancillary, ground sites. Our findings are
133 discussed in Sect. 4 and summarized in Sect. 5. An Appendix (Sect. 6) explains how we
134 averaged recordings of near-surface W-band reflectivities and surface-based recordings of
135 snowfall.

136 2 - Site, Aircraft, and Instruments

137 2.1 - Site

138 Analyzed herein are aircraft and ground data from 14/15 December 2016 and from 3
139 January 2017. The ground data were acquired in a forest/prairie ecotone on the eastern slope of
140 the Medicine Bow Mountains in southeast Wyoming (Figs. 1a-b). No ground-based observers
141 were deployed during the two snowfall events analyzed.

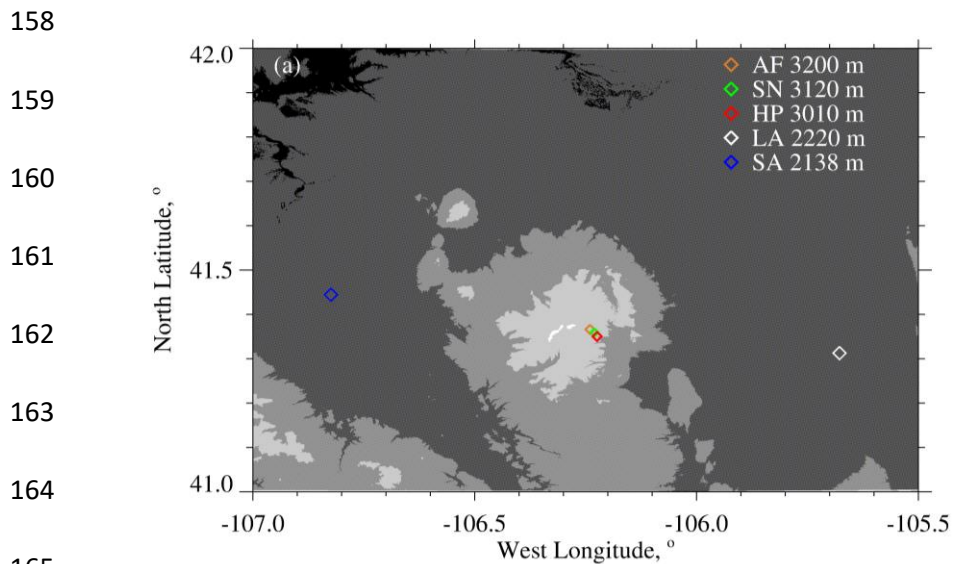

142 At one of three ground sites (HP in Figs. 1a-b) a hotplate precipitation gauge (Rasmussen
143 et al. 2011; Zelasko et al. 2018), a GPS receiver, and a data acquisition system were deployed.
144 Once per second, the data system ingested a hotplate-generated data string, combined that with
145 time-of-day from the GPS receiver [Coordinated Universal Time (UTC)], and recorded the
146 merged hotplate/UTC data string. The absolute accuracy of the time stamp is no worse than 2 s.

147 Overflights of the hotplate were done by the University of Wyoming King Air (WKA) on
148 14/15 December 2016 and on 3 January 2017. The flights were conducted in preparation for the
149 SNOWIE field project (Tessendorf et al. 2019) and were flown from the Laramie, WY Airport
150 (LA in Fig. 1a). Data acquisition on the WKA was also synchronized with UTC, but with much
151 better accuracy than at the hotplate.

152

153 Measurements of horizontal wind (speed and direction), temperature, relative humidity,
154 and pressure from the US-GLE AmeriFlux tower (AF in Figs. 1a-b) are also components the
155 analysis. The AmeriFlux data were provided to us as 30-minute averages (AmeriFlux 2021;
156 Marlow et al. 2023).

157

174 Figure 1 – (a) Southeast Wyoming, airport at Saratoga, WY (SA), airport at Laramie, WY (LA),
 175 and the ground sites: AF = US-GLE AmeriFlux tower, SN = Brooklyn Lake SNOTEL, and HP =
 176 hotplate. Altitudes of the airports and ground sites are in the legend. Altitude thresholds for the
 177 digital elevation map are 1500, 2000, 2500, 3000, and 3500 meters. (b) Close up of the AF, SN,
 178 and HP ground sites (from © Google Earth).

179

180 2.2 - University of Wyoming King Air (WKA)

181 The following WKA measurements were analyzed: aircraft position, temperature, snow
182 particle imagery, and three moments of the cloud droplet size distribution function. A Cloud
183 Droplet Probe (CDP; Faber et al. 2018) was the basis for the droplet size distribution
184 measurements and the derived moments. The latter are droplet concentration (N), cloud liquid
185 water content (LWC), and mean droplet diameter ($\langle D \rangle$). Snow particle imagery was obtained
186 using a precipitation particle imaging probe (2DP; Korolev et al. 2011) and a cloud particle
187 imaging probe (2DS; Lawson et al. 2006). These acquired two-dimensional images of particles
188 between 200 to 6400 μm (2DP) and between 10 to 1280 μm (2DS).

189 2.3 – The W-band Wyoming Cloud Radar (WCR)

190 Retrievals from the up-looking and down-looking antennas of the WCR, operated on the
191 WKA, were also analyzed. For this we used Level 2 WCR data² with reflectivities recorded as
192 $dBZ = 10 \cdot \log_{10}(Z)$. The reflectivities were converted from dBZ to Z prior to processing.
193 Additionally, values of the vertical-component Doppler velocity retrieved from below the WKA
194 using the WCR's down-looking antenna were analyzed. The Doppler velocities were corrected
195 for aircraft motion as described in Haimov and Rodi (2013). We use V_D to symbolize the
196 corrected vertical-component Doppler velocity and adopt the convention that $V_D > 0$ indicates
197 upward hydrometeor motion.

198

² http://flights.uwyo.edu/uwka/wcr/projects/snowie17/PROCESSED_DATA/

199 The Level 2 WCR sampling was different on the two flight days and this difference is
200 shown in Table 1. Ground-based calibrations of the WCR's up-looking antenna and correlations
201 between in-flight retrievals acquired using the WCR's up-looking and down-looking antennas
202 were used to estimate the precision and absolute accuracy of the WCR-derived values of dBZ.
203 These are ± 1.0 dBZ and ± 2.5 dBZ, respectively (PV11).

204

208

209 **2.4 - Hotplate Gauge**

210 Algorithms used to process hotplate measurements are described in Rasmussen et al.
211 (2011), Boudala et al. (2014), and Zelasko et al. (2018). Henceforth, these are referred to as R11,
212 B14, and Z18, respectively. This section describes how hotplate measurements acquired at the
213 HP site were analyzed. The hotplate deployed at the HP site is described in Wolfe and Snider
214 (2012), Z18, and in Marlow et al. (2023).

215 Five measurements fundamental to the steady state energy budget of the hotplate's
216 temperature-controlled up-viewing plate are output by the hotplate microprocessor as one-minute
217 running averages (Z18). These averages were merged with the GPS time and recorded at 1 Hz by
218 the data acquisition system (Sect. 2.1). With these measurements, calibration data (Marlow et al.
219 2023), and the algorithm developed by Z18, we calculated S in two steps. First, the five hotplate
220 measurements (electrical power supplied to the plate, ambient temperature, wind speed,
221 downwelling shortwave flux, and downwelling longwave flux) were input to Eq. 3 in Z18. The
222 output of that equation is a provisional liquid-equivalent precipitation rate. Second, the snow
223 particle catch efficiency, described in the next paragraph, was used to calculate S as the ratio of
224 the provisional rate and the catch efficiency.

225 Marlow et al. (2023; their Fig. 3b) report the relationship between snow particle catch
226 efficiency and wind speed that was applied in the calculation of S . There are three bases for this
227 relationship. First is the catch efficiencies R11 derived using measurements obtained from a
228 weighing gauge, operated within a double fence intercomparison reference shield, and collocated
229 measurements from an unshielded hotplate gauge. These paired measurements are symbolized
230 SRG (shielded reference gauge) and UHG (unshielded hotplate gauge). R11 plotted hotplate
231 catch efficiencies (i.e., UHG/SRG) versus wind speeds measured at 10 m AGL (their Fig. 8).

232 Second is Marlow et al.'s adjustment of R11's 10 m AGL wind speeds to 2 m AGL. The basis
233 for the adjustment is surface boundary layer parameters derived for R11's site (Kochendorfer et
234 al. 2018) and an equation from Panofsky and Dutton (1984; their Eq. 6.7). The adjustment was
235 made because the hotplate-derived wind speeds, both here and in Marlow et al. (2023), were
236 acquired at approximately 2 m above the snowpack surface. Third is Marlow et al.'s comparison
237 of SNOTEL-derived liquid-equivalent depth changes and hotplate-derived time-integrated
238 accumulations. The interval for the comparisons is 24 hours. Based on the comparison, which
239 has 57 paired values acquired at the sites labeled HP and SN in Fig. 1, the average fractional
240 absolute relative difference is 0.30. Marlow et al. also provided an estimate of the error in a
241 SNOTEL measurement (2.4 mm). At accumulation = 10 mm the error corresponds to a relative
242 error = 0.24. This indicates that SNOTEL contributed significantly to the SNOTEL/hotplate
243 variance and especially so for the smaller accumulations in Fig. 9a of Marlow et al. (2023).
244 Because of this, we do not limit the following estimate of hotplate precision to a subset of the 57
245 paired measurements. Based on our assessment of the average fractional absolute relative
246 difference, the hotplate precision applied in this analysis was taken to be 0.3.

247 The hotplate-derived wind speeds acquired at ~ 2 m, and discussed in the previous
248 paragraph, are henceforth symbolized U_{PRO} . The basis for these is a steady state energy budget of
249 the hotplate's temperature-controlled down-viewing plate and a proprietary algorithm (R11 and
250 Z18). The U_{PRO} are reported by a hotplate as one-minute running averages (Z18) and we
251 recorded these at 1 Hz. Examples are the gray dots in Fig. 2. Additionally, we calculated and
252 analyzed one-minute-averaged values of U_{PRO} and the corresponding standard deviations.
253 Examples of these are the black circles and the short vertical line segments in Fig. 2.

254

Figure 2 – Hotplate wind speed measurements (U_{PRO}) 00:00:00 to 00:04:00 on 15 December 2016. Gray dots are the one-minute running-average U_{PRO} recorded at 1 Hz. Black circles are the one-minute-averaged U_{PRO} (± 1 standard deviation).

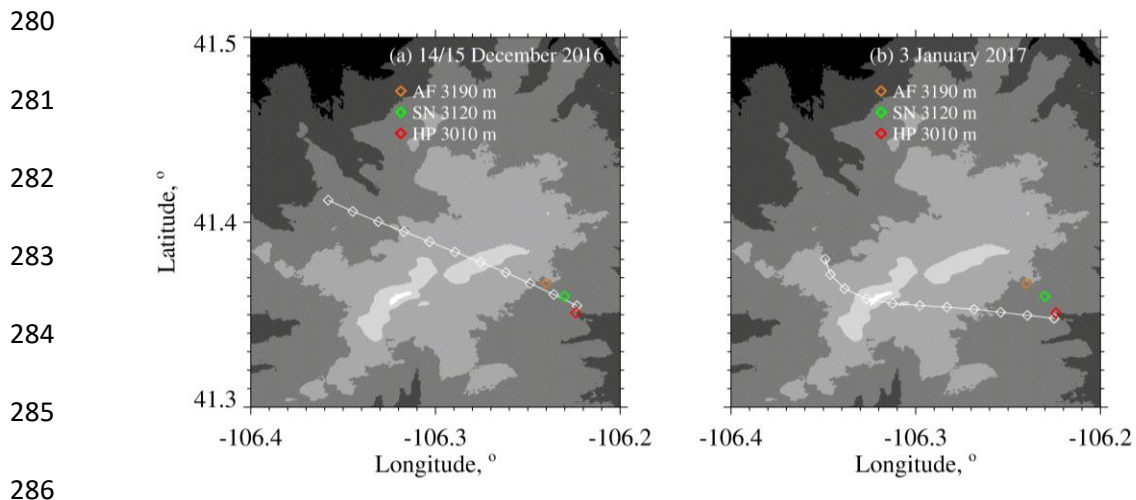

265 **3 - Analysis**

266 **3.1 - WKA Overflight Time**

267 The focus of our analysis is the two WKA flight segments shown in Figs. 3a-b. The maps
268 shown in the figures have the three ground sites (AF, SN, and HP) and the WKA flight tracks
269 (white line). The beginning-to-end time interval for the flight tracks is 100 s and these are
270 divided into ten 10-second intervals. The 10 s intervals are indicated with white diamonds.
271 Except for the turn evident in Fig. 3b, the flight tracks are straight, and the track direction is
272 approximately upwind to downwind.

273 Times that the WKA was closest to the HP site were evaluated by finding the point on the
274 flight track where the horizontal position of the WKA was closest to the hotplate's coordinates.
275 These times are symbolized t_o and are referred to as overflight times. In Figs. 3a-b the
276 downwind end of the flight tracks end at the overflight time. The latitude/longitude position of
277 the aircraft was within 390 m of the hotplate at the overflight times. Table 1 has the overflight
278 times on the two flight days.

279

287 Figure 3 – (a) WKA flight track on 14/15 December 2016 for time interval = overflight time -
 288 100 s to the overflight time. (b) WKA flight track on 3 January 2017 for time interval =
 289 overflight time - 100 s to the overflight time. The white diamonds on the tracks are separated, in
 290 time, by 10 s. Altitude thresholds for the digital elevation maps are 2600, 2800, 3000, 3200,
 291 3400, and 3600 meters. Altitudes of the ground sites are in the legend.

292

293 3.2 – Effect of Attenuation on WCR Reflectivities

294

295 The presence of molecular oxygen, water vapor, cloud water, and snow particles within
296 the WCR's transmission path will contribute to an attenuation of microwave intensity and will
297 therefore negatively bias the retrieved reflectivities (Matrosov 2007; Hiley et al. 2011; Kneifel et
298 al. 2015). Models of attenuation, radar remote sensing, and in situ measurements were used to
299 calculate this bias. For oxygen, an attenuation coefficient from Ulaby et al. (1981; their Fig. 5.6),
300 and temperature (T) and pressure (P) measurements from the AF (Table 2), were used. For
301 vapor, an attenuation coefficient (Ulaby et al. 1981; their Eq. 5.22), and T, P, and relative
302 humidity (RH) measurements from the AF (Table 2), were used. Concentrations of oxygen and
303 water vapor and the oxygen and vapor path lengths are provided in Table 3. The latter is the
304 vertical distance between the HP and the WKA. It was assumed that concentrations were
305 uniform over this path length.

306 Attenuation by cloud water was derived using the WKA-measured T (Table 2), the
307 WKA-measured LWC, path length (Table 3), and an attenuation formula (Liebe et al. 1989; Vali
308 and Haimov 2001). The LWC applied in the formula is the maximum of CDP measurements
309 acquired between $t_o - 10$ s and t_o . This interval coincides with the interval the WCR's down-
310 looking antenna was used to acquire reflectivities over the HP (Sect. 3.5). The path length for
311 cloud water was derived as the vertical distance between cloud base [derived thermodynamically
312 using AF measurements (Table 2)] and flight level. LWC was assumed uniform, at the maximum
313 value, over the path length.

314 Snow particle mass concentration is typically reported as an ice water content (IWC, g m^{-3})
315 (Liu and Illingworth 2000). The contribution of IWC to attenuation was calculated using

316 measurements in Nemanich et. al (1988), who reported an attenuation coefficient equal to 0.9
 317 dB/km per unit of IWC. Also used were retrievals of IWC acquired using the down-pointing
 318 WCR antenna. There are several steps in the calculation. First, all profiles of dBZ acquired
 319 between $t_o - 10$ s and t_o were selected. Second, a maximum dBZ was selected at each of the
 320 down-beam range gates (Table 1). Third, the dBZ maxima were increased by the overall two-
 321 way attenuation in the final column of Table 3. Fourth, the profile of attenuation-corrected dBZ
 322 was converted to a profile of attenuation-corrected Z. Fifth, a Z-to-IWC parameterization was
 323 applied ($IWC = 0.10 \cdot Z^{0.51}$; PV11; their Table 3). Sixth, the IWC profile was integrated, and the
 324 derived ice water path was divided by the snow particle path length (Table 3). This calculation
 325 produced a time- and range-averaged maximum IWC (Table 3). This IWC is the value applied in
 326 the attenuation calculation.

327 Two-way attenuations (ΔdB), summed over contributions from the four components, are
 328 presented in the final column of Table 3. Attenuation by snow and attenuation by liquid were the
 329 most important components ($> 50\%$) on December 15 and January 3, respectively. Vapor
 330 contributed 32% to the overall on December 15, and the combination of vapor and snow
 331 contributed 45% on January 3. Equation 1 shows how an attenuation-corrected reflectivity (Z')
 332 was derived using an uncorrected reflectivity (Z) and the ΔdB .

333

$$334 \quad Z' = 10^{\left[\frac{10 \cdot \log_{10}(Z) + \Delta dB}{10} \right]} \quad (1)$$

 341 minus 60 s, and ends at the overflight time.

342

343 ^b Temperature (T), relative humidity (RH), and horizontal wind vector data from sensors on the
 344 US-GLE AmeriFlux tower (Sect. 2.1). The wind sensor was deployed at 26 m AGL (3223 m
 345 MSL) and the T/RH sensor was deployed at 23 m AGL (3220 m MSL). The AF measurements
 346 correspond to 30-minute averages closest to the overpass time. In the AF data set time stamps on
 347 the relevant AF recordings are 00:00 UTC (15 December 2016) and 20:30 UTC (3 January
 348 2017).

349

350 ^c Vectors are presented in the following format: Direction of motion (degree relative to true
 351 north) / speed (m s^{-1}).

352 Table 3 – Attenuating component concentration, one-way pathlength, and the overall two-way attenuation

Date	Conc. Oxygen, kg m ⁻³	Conc. Vapor, kg m ⁻³	Maximum LWC, g m ⁻³	Maximum IWC, g m ⁻³	One-way Pathlength ^a Oxygen, Vapor, and Snow, km	One-way Pathlength ^b Cloud Water, km	Overall Two-way Attenuation, ΔdB

355

356 ^b Vertical distance between cloud base [derived thermodynamically using AF measurements (Table 2)] and WKA

357

358 ^c One-way attenuation coefficients are 0.03 dB/km for oxygen (Ulaby et al. 1981), 0.14 dB/km for vapor (Ulaby et al. 1981), 0.056
359 dB/km for cloud water (Liebe et al. 1989; Vali and Haimov 2001), and 0.24 dB/km for snow particles (Nemarich et. al 1988).

360

361 ^d One-way attenuation coefficients are 0.03 dB/km for oxygen (Ulaby et al. 1981), 0.073 dB/km for vapor (Ulaby et al. 1981), 0.49
362 dB/km for cloud water (Liebe et al. 1989; Vali and Haimov 2001), and 0.077 dB/km for snow particles (Nemarich et. al 1988).

363

364 **3.3 - Correction of Doppler Velocity**

365 We accounted for bias in V_D (Sect. 2.3) due to deviation of the down-looking WCR
366 antenna from vertical. This was done by applying the correction described in Zaremba et al.
367 (2022) (their Eq. A4). The west-to-east and south-to-north particle velocities used in the
368 correction were assumed to be equal to component wind velocities. The latter were expressed as
369 linear functions of altitude using the information in the penultimate and last columns of Table 2.
370 The component velocities as functions of altitude and the linear equations relating velocity and
371 altitude are provided in the Appendix.

372 **3.4 - Hotplate Measurement of Wind Speed**

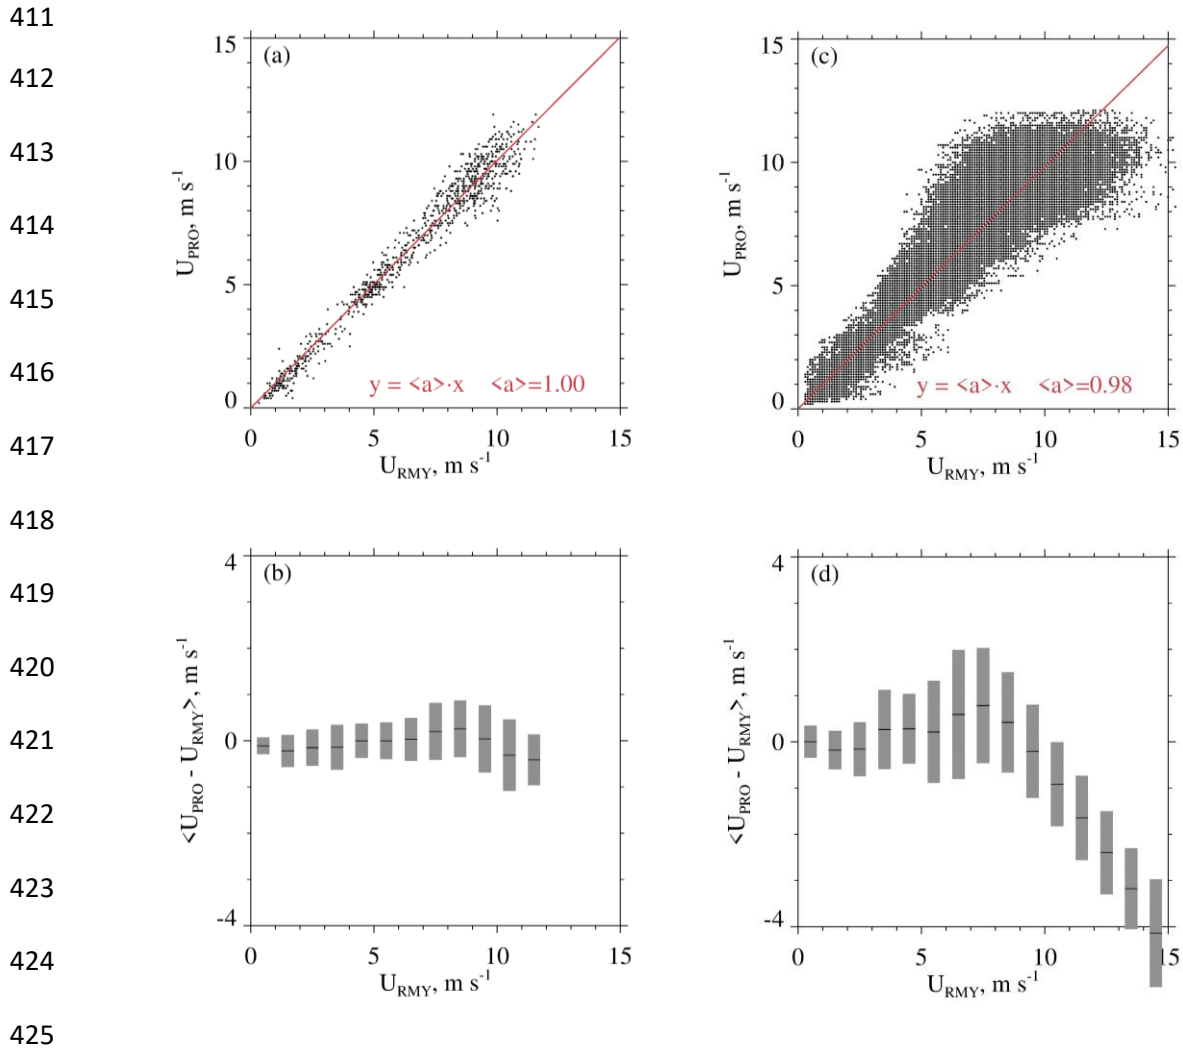

373 Here we compare the hotplate-derived wind speed to wind speed derived using an
374 R.M.Young rotating anemometer (R.M.Young 2001). The second of these is symbolized U_{RMY}
375 and the basis for the first (U_{PRO}) is a proprietary algorithm (Sect. 2.4). We are doing this
376 comparison because B14 showed that U_{PRO} can be high-biased, relative to a conventional
377 anemometer, and because U_{PRO} is the primary determinant of the rate that the up-viewing plate
378 dissipates sensible heat energy. Diagnosis of that heat transfer rate is our basis for calculating the
379 liquid-equivalent snowfall rate (Z18). The U_{PRO} also determines the snow particle catch
380 efficiency and the latter was used in calculations of the undercatch-corrected liquid-equivalent
381 snowfall rate (Sect. 2.4).

382 The comparisons reported here were done at the Laramie, WY Airport in December
383 2019, and in January 2020. Compared to the HP site, the Laramie Airport site (indicated LA in
384 Fig. 1) is free of obstruction, out to 120 m, and experiences larger wind speeds. By mounting the
385 hotplate and the R.M.Young anemometer on rigid metal pipes, the hotplate's heated horizontal

386 surfaces (the up- and down-viewing plates seen in Fig. 1 of Z18) and the anemometer's spinning
387 axis (oriented horizontally) were both positioned at 2 m AGL. The pipes were separated
388 horizontally by 5 m. There was no precipitation on the days selected for the wind speed
389 comparisons. The values of U_{PRO} and U_{RMV} we analyzed were recorded with a data system that
390 time stamped the 1 Hz U_{PRO} and 1 Hz U_{RMV} with a relative timing accuracy no worse than 1 s.

391 A wind speed comparison - from 13 December 2019 - is shown in Fig. 4a. U_{PRO} was
392 brought into the comparison by sampling it once per minute from files containing 1 Hz
393 recordings of the one-minute running-average U_{PRO} (Sect. 2.4). U_{RMV} was brought into the
394 comparison by starting with files containing 1 Hz recordings and converting these to one-minute
395 averages. Fig. 4a shows no evidence of bias and Fig. 4b demonstrates that the average absolute
396 departure between the U_{PRO} and U_{RMV} (both one-minute averages) is no larger than 0.5 m s^{-1} .
397 Table 4 has eight more precipitation-free comparisons. Included in the table are temperature and
398 wind speed averaged over the comparison intervals (4 to 20 UTC), the slope of the linear-least-
399 squares fit line (forced through the origin, red line), and the lower and upper quartiles of the
400 slope. The quartiles were calculated using the method of Wolfe and Snider (2012). In contrast to
401 Figs. 4a-b, Figs. 4c-d make the comparison using 1 Hz values of U_{PRO} and U_{RMV} . The larger
402 scatter and larger average absolute departure seen in these panels is a consequence of the
403 hotplate's limited time response, compared to the R.M.Young. We quantify the hotplate's
404 response time in terms of a calculated thermal response time. During wintertime at the Laramie
405 Airport, and with wind speed at 5 m s^{-1} , the down-viewing plate's thermal response time is
406 approximately 60 s (results not shown). Because the temperature of the down-viewing plate is
407 actively controlled, this does not translate to a 60 s lag between changes in wind speed and the
408 hotplate response. The $U_{\text{PRO}}/U_{\text{RMV}}$ departure is most evident at $U_{\text{PRO}} > 5 \text{ m s}^{-1}$ (Fig. 4d) but this is

- 409 not a concern for U_{PRO} on 14/15 December 2016 or on 3 January 2017. Snider (2023)
- 410 demonstrated that the U_{PRO} was less than 5 m s^{-1} at the hotplate during the two WKA overflights.

426 Figure 4 – (a) Scatterplot of one-minute-averaged U_{PRO} and one-minute-averaged U_{RMY} .
 427 Measurements were acquired at the Laramie, WY Airport 13 December 2019. The red line is a
 428 linear-least-squares fit line (forced through the origin). (b) Average departure between one-
 429 minute-averaged U_{PRO} and one-minute-averaged U_{RMY} . Average departures were calculated for
 430 discrete U_{RMY} intervals, and the averages are indicated with short black horizontal lines. Gray
 431 bars indicate ± 1 standard deviation. (c) Same as in (a) except 1 Hz values of U_{PRO} and U_{RMY} . (d)
 432 Same as in (b) except for 1 Hz values of U_{PRO} and U_{RMY} .

448

449 3.5 – Combined Aircraft and Surface Measurements

450 Figure 5 has WCR and WKA measurements starting 100 s prior to t_o and ending at t_o .
451 The sequences in Figs. 5a and 5c are reflectivities from both the up- and down-looking antennas.
452 In Fig. 5a the flight track (black dashed horizontal line) is at 4550 m and in Fig. 5c the flight
453 track is at 4200 m. At the t_o in Fig. 5a, below the WKA, the maximum radar echo is +6 dBZ ($Z =$
454 $4 \text{ mm}^6 \text{ m}^{-3}$) and in Fig. 5c the maximum is -3 dBZ ($Z = 0.5 \text{ mm}^6 \text{ m}^{-3}$). Supercooled liquid water
455 was detected as the aircraft approached the ridgeline (Fig. 5b) and during the last 10 seconds of
456 the time sequence in Fig. 5d. During these encounters with supercooled liquid, the maximum
457 LWC values were 0.03×10^{-3} and $0.08 \times 10^{-3} \text{ kg m}^{-3}$ on 14 December 2016 and 3 January 2017,
458 respectively. Values of N (Sect. 2.2) at times of maximal LWC were 3×10^6 and $100 \times 10^6 \text{ m}^{-3}$ on
459 14 December 2016 and 3 January 2017, respectively. Even on 3 January 2017, the $\langle D \rangle$ (Sect.
460 2.2) associated with maximum LWC was sufficient for hexagonal plate crystals with diameter
461 larger than $100 \text{ }\mu\text{m}$ to collide with the observed droplets with efficiencies > 0.1 (Wang and Ji
462 2000).

463 We temporally and spatially averaged the values of Z we compared with time-averaged
464 values of S . There are two reasons for this: 1) As discussed in Sect. 3.1, the WCR did not sample
465 Z exactly over the hotplate, and furthermore, the width of radar beam at 1500 m range - roughly
466 the distance between the aircraft and the ground at the overflight times - is 30 m and thus
467 considerably smaller than the minimum horizontal distance between the aircraft and the HP. 2)
468 Compared to the WCR, the hotplate is a relatively slow-response measurement system whose
469 output is commonly averaged over one-minute intervals (Z18).

470

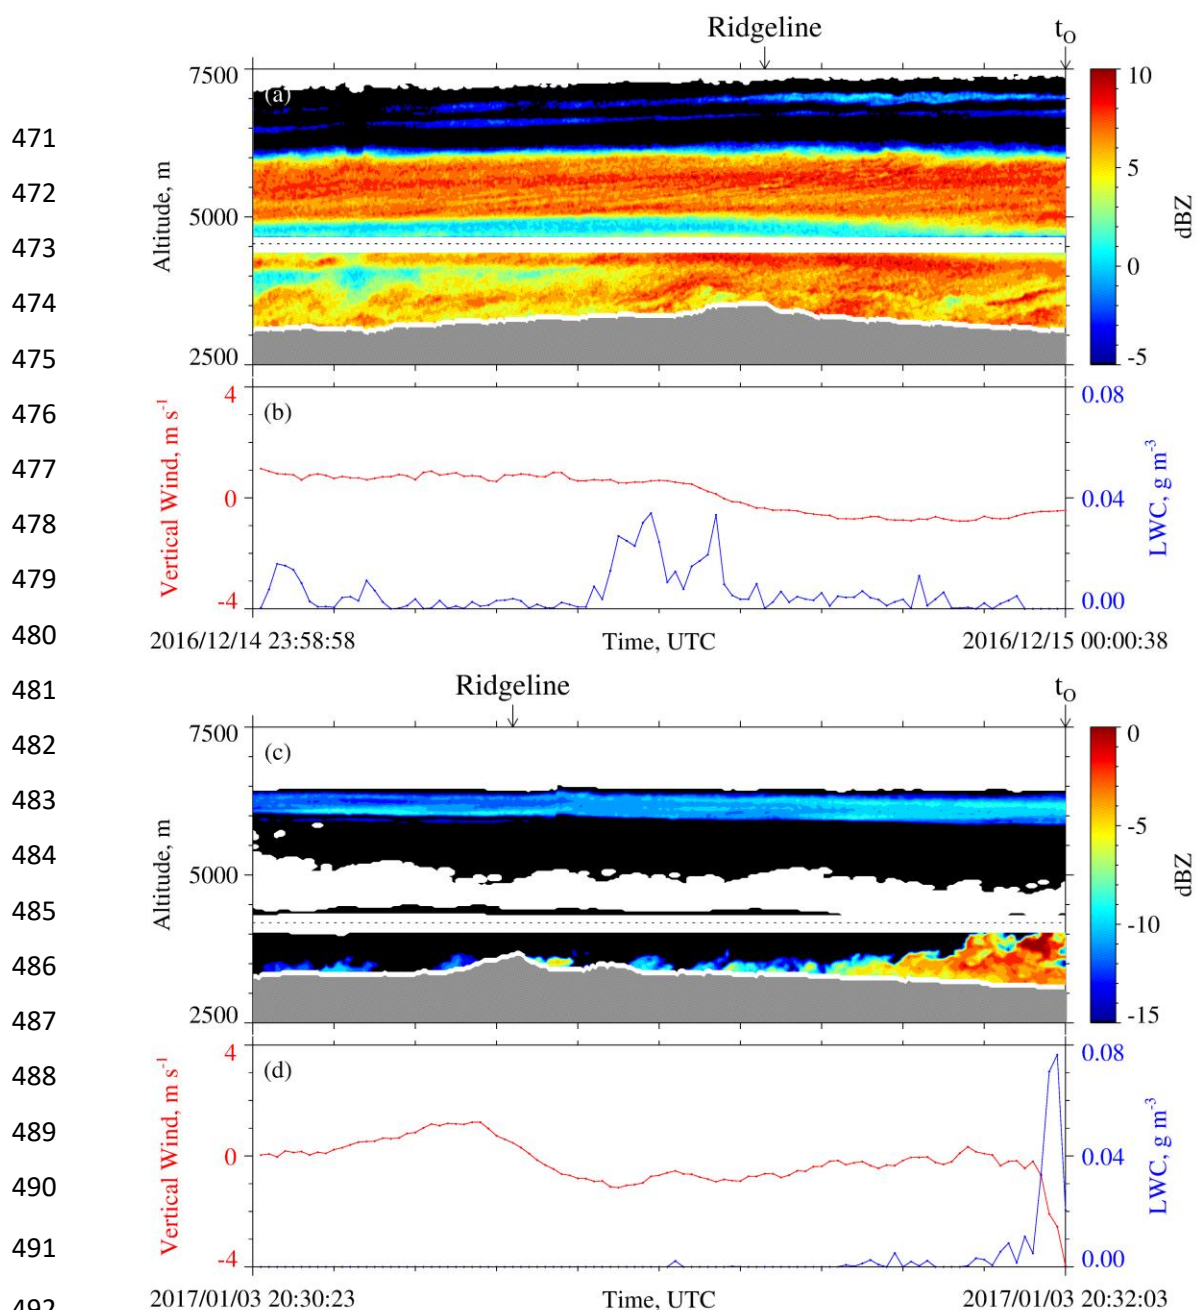

Figure 5 – (a) 100 s of WCR reflectivity and (b) 100 s of LWC and gust probe vertical wind velocity ending at t_0 on 14/15 December 2016. (c) 100 s of WCR reflectivity and (d) 100 s of LWC and gust probe vertical wind velocity ending at t_0 on 3 January 2017. In (a) and (c), above and below the flight track, is the roughly 200-m-deep WCR blind zone, reflectivity above (below) the flight track is from the up-looking (down-looking) WCR antenna, black indicates dBZ values smaller than minimum indicated in the color bar, white immediately above the terrain indicates echo that was discarded because of ground clutter, and white above the ground clutter and outside of the blind zone indicate dBZ < minimum detectable signal.

503 The HP measurements were averaged over two adjacent 60 s intervals. The first extends
504 from t_0 to $t_0 + 60$ s (Fig. 6a) and the second from $t_0 + 60$ s to $t_0 + 120$ s (Fig. 6c). In Fig. 6a and
505 in Fig. 6c, $t_{HP,B}$ symbolizes an interval's beginning time and $t_{HP,E}$ symbolizes an interval's
506 ending time. Formulas describing how these times were related to the beginning and ending time
507 of a corresponding WCR averaging interval are in the Appendix. Fig. 6b is a schematic of the
508 first WCR averaging interval and Fig. 6d is a schematic of the second. Again, the subscripts "B"
509 and "E" are used to indicate averaging beginning and ending times. Figures 6b and 6d both have
510 lines at the top of an averaging interval/domain. The slopes of these lines are proportional to the
511 ratio of two speeds. These speeds are a maximum likely snow particle speed toward the ground (v_p)
512 and a horizontal wind advection speed (v_w). The v_p was calculated using averaged vertical-
513 component Doppler velocities and v_w was calculated using a vertical profile of horizontal winds,
514 based on WKA horizontal wind measurements and AF horizontal wind measurements (Figs.
515 A1a-b), and using the WKA track vector (Table 2). An altitude ($z' = 3400$ m) was assumed in the
516 calculation of v_w . This is the altitude of the ridges west and northwest of the HP site (Figs. 3a-
517 b). Picking the altitude to be either $z' = 3200$ m or $z' = 3600$ m does not alter our findings.

Figure 6 – (a and c) Representations of the $i = 0$ and $i = 1$ HP averaging intervals. (b and d) Representations of the $i = 0$ and $i = 1$ WCR averaging intervals/domains. The t_0 is shown in all panels. The subscripts “B” and “E” indicate beginning and ending times of HP averaging (panels a and c) and the beginning and ending times of WCR averaging (panels b and d).

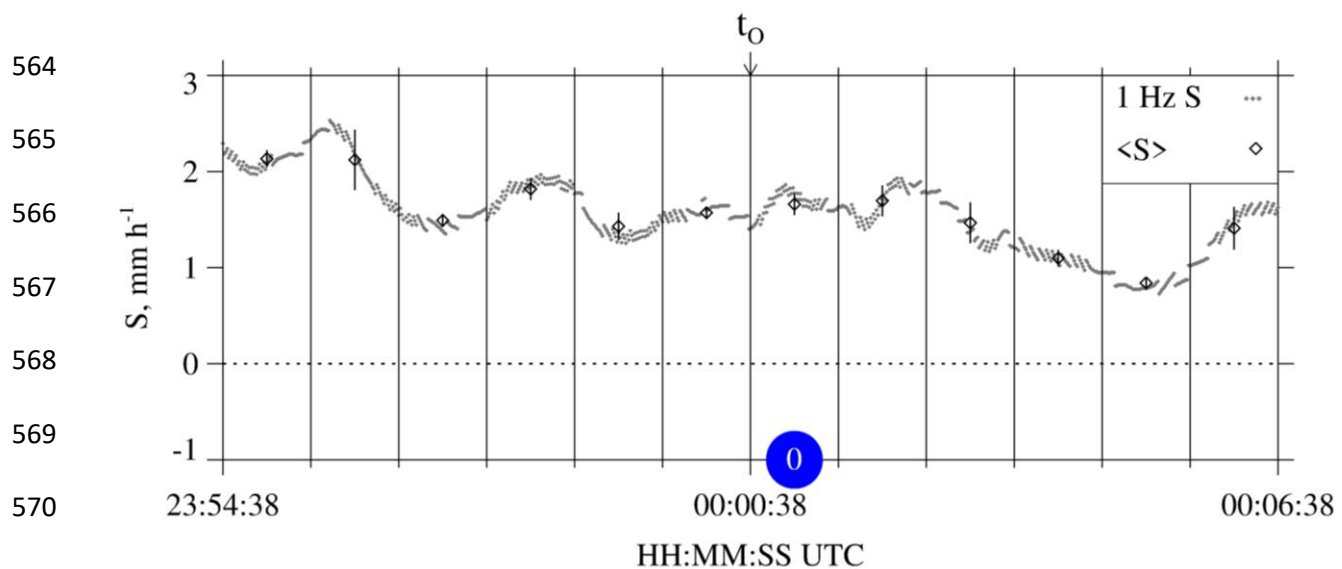

544

545 All panels in Fig. 6 are labeled with an index designating either the first averaging
546 interval ($i = 0$) or the second averaging interval ($i = 1$). Figures 7 and 8 present hotplate
547 snowfall measurements from 14/15 December 2016 and 3 January 2017. In these, and in
548 subsequent figures, colored circles surround the indexes, blue is used to color-code 15 December
549 2016, and red is used to color-code 3 January 2017. Additionally, Fig. 8 has an $i = 2$ averaging
550 interval. This is a special case discussed at the end of this section.

551 Figures 9a-b and Figs. 10a-b have enlarged views of the altitude-time crosssections
552 recorded on the two flight days. Different from Fig. 5a and Fig. 5c, these measurements are only
553 from the WCR's down-looking antenna. Additional differences are the following: 1) The plots
554 are set up so that Z and V_D structures downwind of the hotplate can be seen. These structures are
555 discussed in the following section. 2) The WCR measurements are shown for 50 s of flight. With
556 the WKA ground speed approximately 125 m s^{-1} (Table 2), the distance along the abscissa is
557 6250 m. 3) Colored circles that surround the $i = 0$ index are placed below the WCR averaging
558 intervals/domains. The latter are drawn with solid black lines and are seen to overlay both the Z
559 and V_D altitude-time crosssections. Consistent with Figs. 6b and 6d, and the Appendix, one of
560 these black lines is vertical and the other is negatively sloped. Figs. 10a-b also have the $i = 2$
561 intervals/domains discussed at the end of this section.

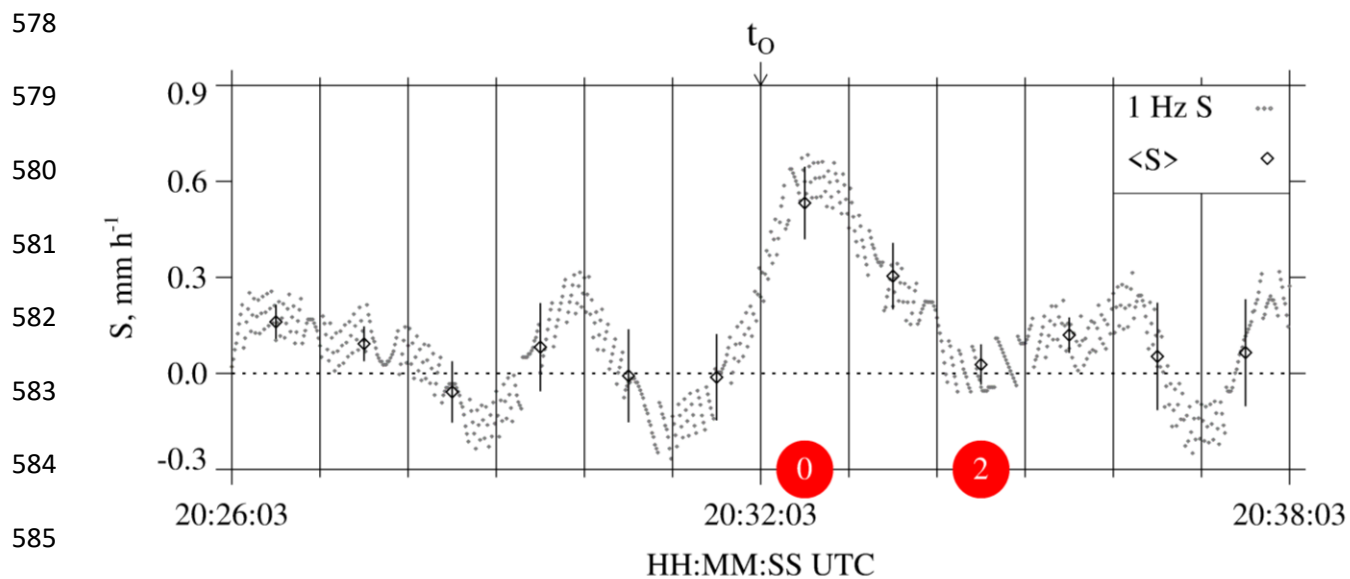

562

563

573 Figure 7 – Twelve minutes of HP snowfall measurements from 14/15 December 2016. Gray dots
 574 are S values calculated using hotplate output recorded at 1 Hz. Black diamonds are the one-
 575 minute-averaged values (± 1 standard deviation). The t_0 is shown above the panel and the blue
 576 circle designates the $i = 0$ HP averaging interval.

577

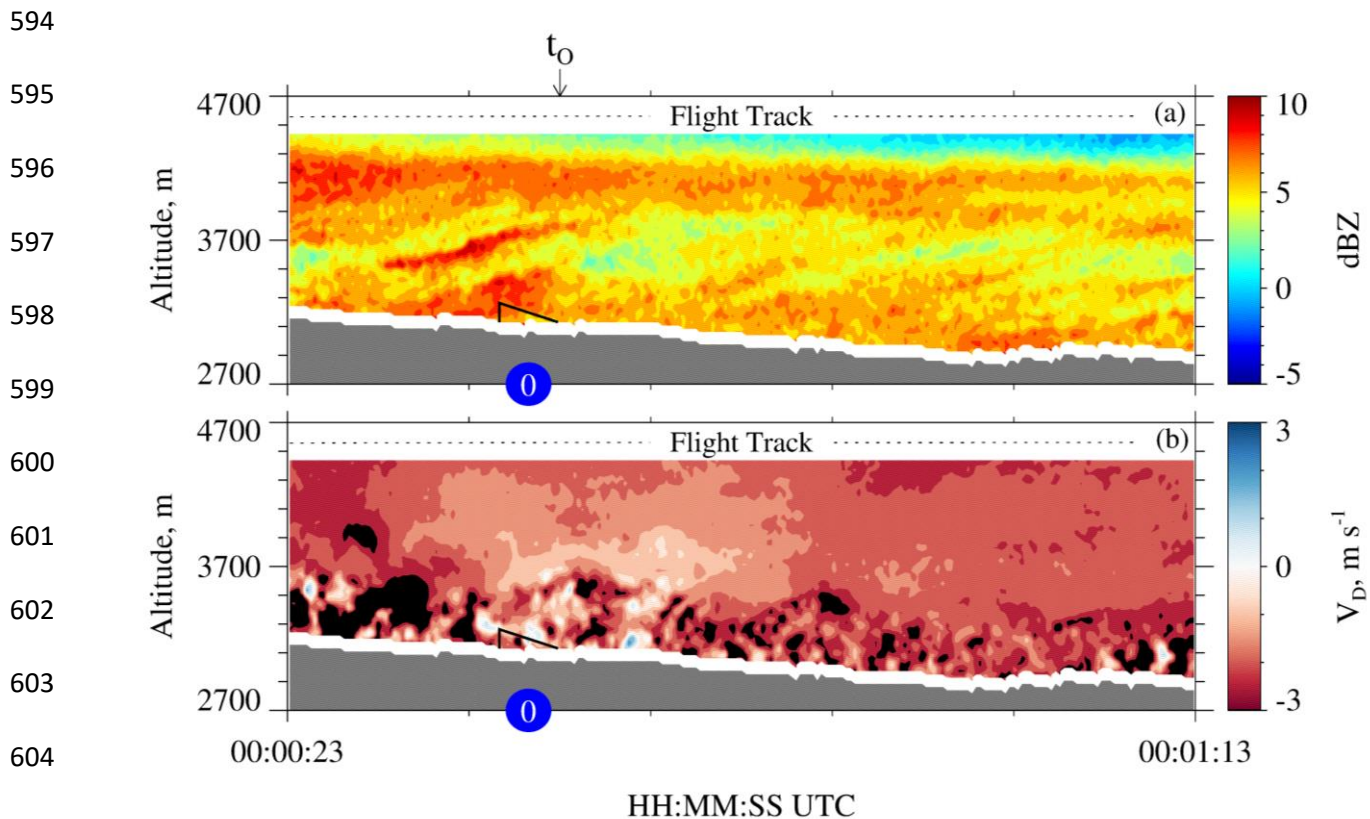

588 Figure 8 – Twelve minutes of HP snowfall measurements from 3 January 2017. Gray dots are S

589 values calculated using hotplate output recorded at 1 Hz. Black diamonds are the one-minute-

590 averaged values (± 1 standard deviation). The t_0 is shown above the panel, a red circle designates

591 the $i = 0$ HP averaging interval, and a red circle designates the $i = 2$ HP averaging interval. The

592 latter is a special case discussed at the end of Sect. 3.5.

608 Figure 9 – 50 s of measurements from the down-looking WCR antenna on 15 December 2016.

609 (a) Cross-section of reflectivity $t_0 - 15$ s to $t_0 + 35$ s. (b) Cross-section of Doppler velocity $t_0 - 15$ s to

610 $t_0 + 35$ s. The t_0 is shown above the top panel. In both panels, the solid black lines (vertical and

611 sloped) encompass the $i = 0$ WCR averaging interval/domain and blue circles designate the

612 $i = 0$ WCR averaging interval.

613

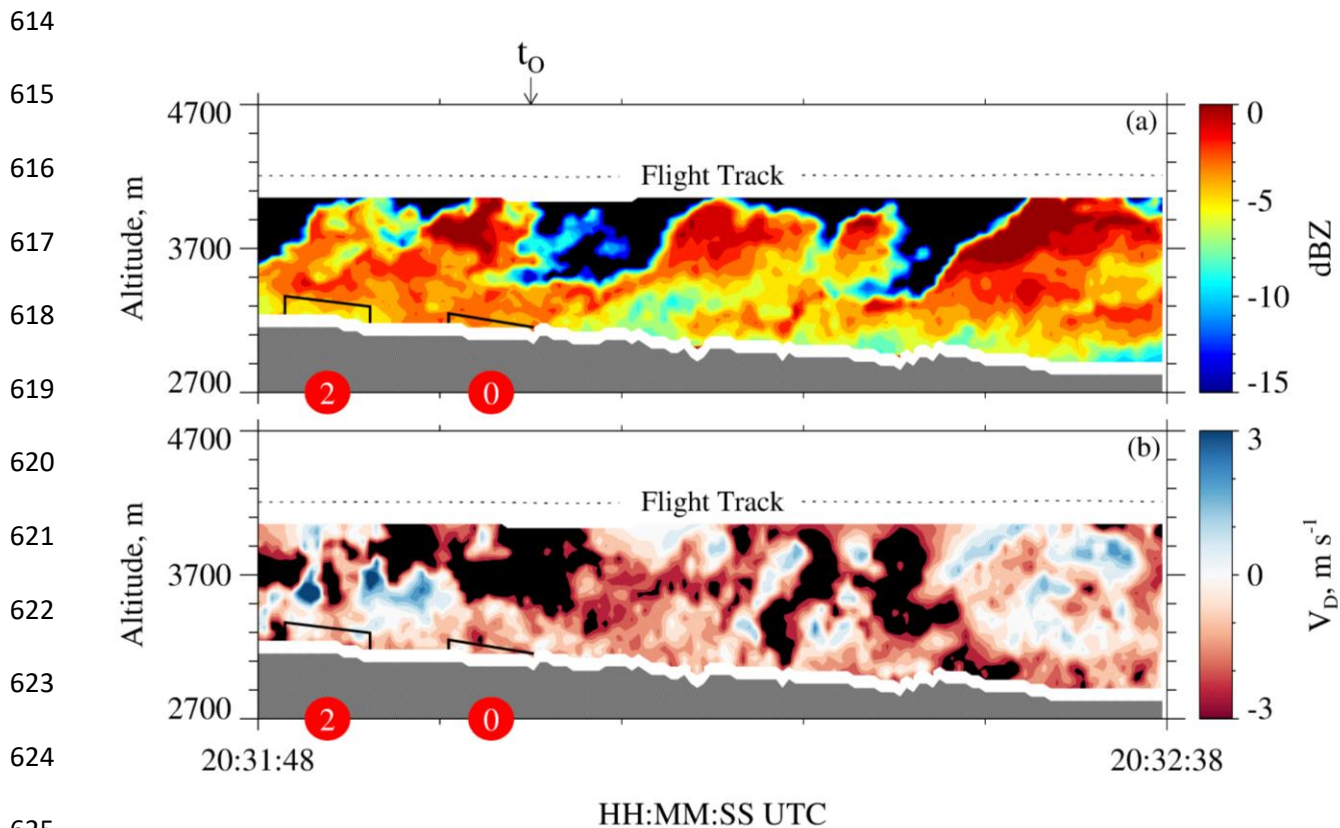

Figure 10 – 50 s of measurements from the down-looking WCR antenna on 3 January 2017. (a) Crossection of reflectivity $t_0 - 15$ s to $t_0 + 35$ s. (b) Crossection of Doppler velocity $t_0 - 15$ s to $t_0 + 35$ s. The t_0 is shown above the top panel. In both panels, the solid black lines (vertical and sloped) encompass the $i = 0$ and $i = 2$ WCR averaging intervals/domains, two red circles designate the $i = 0$ WCR averaging interval, and two red circles designate the $i = 2$ WCR averaging interval. The $i = 2$ intervals/domains are a special case discussed at the end of Sect. 3.5.

635 The $i = 0$ averages of S and Z are presented in Table 5 and the corresponding averaging
636 intervals are viewable in Fig. 7 and Fig. 9a (15 December 2016) and in Fig. 8 and Fig. 10a (3
637 January 2017). The $i = 1$ averages are also presented in Table 5. According to the averaging
638 scheme (Fig. 6), the $i = 1$ HP averaging interval is time-shifted positively compared to the $i = 0$
639 HP averaging interval and the $i = 1$ WCR averaging interval is time-shifted negatively compared
640 of the $i = 0$ WCR averaging interval. This arrangement of the averaging intervals is one way to
641 average while also accounting for wind advection of the snow particles.

642 As discussed earlier in this section, the averaging scheme initializes with 60-second
643 blocks of HP data between t_0 and $t_0 + 120$ s. When we applied the scheme to data from 3 January
644 2017, but outside the specified time range, an inconsistency was documented. This is apparent in
645 Fig. 8, where the $t_0 + 120$ s to $t_0 + 180$ s interval (i.e., the $i = 2$ interval) has negligible average S,
646 while in Fig. 10, the $i = 2$ interval has a non-negligible average Z ($\sim 0.3 \text{ mm}^6 \text{ m}^{-3}$). A firm
647 explanation is not available for the inconsistency, but a factor may be the convective nature of
648 the fields in Figs. 10a-b. Because of the inconsistency, only averages corresponding to the $i = 0$
649 and $i = 1$ intervals were analyzed further.

650

658 deviation). An example averaging interval is the interval in Fig. 7.

659

660 ^c Number of samples used to calculate WCR statistics in the penultimate four columns. The
661 averaging intervals/domains (e.g., $i = 0$ in Figs. 9a-b and in Figs. 10a-b) encompass the averaged
662 WCR samples.

663

664 ^d Average of Doppler velocity within the averaging intervals/domains.

665

666 ^e Standard deviation of Doppler velocity within the averaging intervals/domains.

667

668 ^f Maximum likely snow particle speed toward the ground (Eq. A8).

669

670 ^g Average reflectivity (± 1 standard deviation). These values are not corrected for attenuation.

671

672 3.6 - Snow Particle Imagery

673 In Fig. 9a and Fig. 10a, the time for a snow particle to move the abscissa and ordinate
 674 distances is different. The ratio of these two times is 2.6. This follows from our choice of
 675 abscissa and ordinate ranges, from values of particle fall speed (1 m s^{-1}) and horizontal wind
 676 advection speed (8 m s^{-1}), which we assumed, and from the WKA ground speed ($gs \sim 125 \text{ m s}^{-1}$;
 677 Table 2). The assumed values are approximately consistent with values of $\langle V_D \rangle$ and v_w , in
 678 Table 5, and with the V_D sign convention (Sect. 2.3). We also used $gs = 125 \text{ m s}^{-1}$ to scale
 679 (virtually) the time axes in Fig. 9a and Fig. 10a to a horizontal distance. Within the scaled
 680 coordinate frames, we assumed that all snow particle trajectories have negative slope ($\Delta z / \Delta x = -$
 681 $1 \text{ m s}^{-1} / 8 \text{ m s}^{-1} = -0.12$) and that all trajectories are stationary. However, both assumptions seem
 682 inconsistent with the reflectivity structures in Fig. 5a, where positively-sloped particle fall
 683 streaks are evident at $\sim 5500 \text{ m}$, inconsistent with Fig. 9a where positively-sloped fall streaks are
 684 at $\sim 3500 \text{ m}$, and inconsistent with the positively-sloped fall streaks in Fig. 10a. On both flight
 685 days, the fall streaks evince particle sources that move horizontally and with a horizontal speed
 686 that is larger than the $v_w = 8 \text{ m s}^{-1}$ applied in the estimate of the trajectory slope. It may be that
 687 the source's horizontal speed is comparable to the flight-level WKA-derived horizontal wind (27
 688 to 32 m s^{-1} ; Table 2) but we do not have data needed to verify that assertion. Based on the
 689 assumption that snow particles followed the fall streaks while both were advecting horizontally,
 690 we looked *downwind* of the hotplate - at a time later than t_o in Fig. 9a and Fig. 10a - for particles
 691 that became those that produced snowfall at the hotplate.

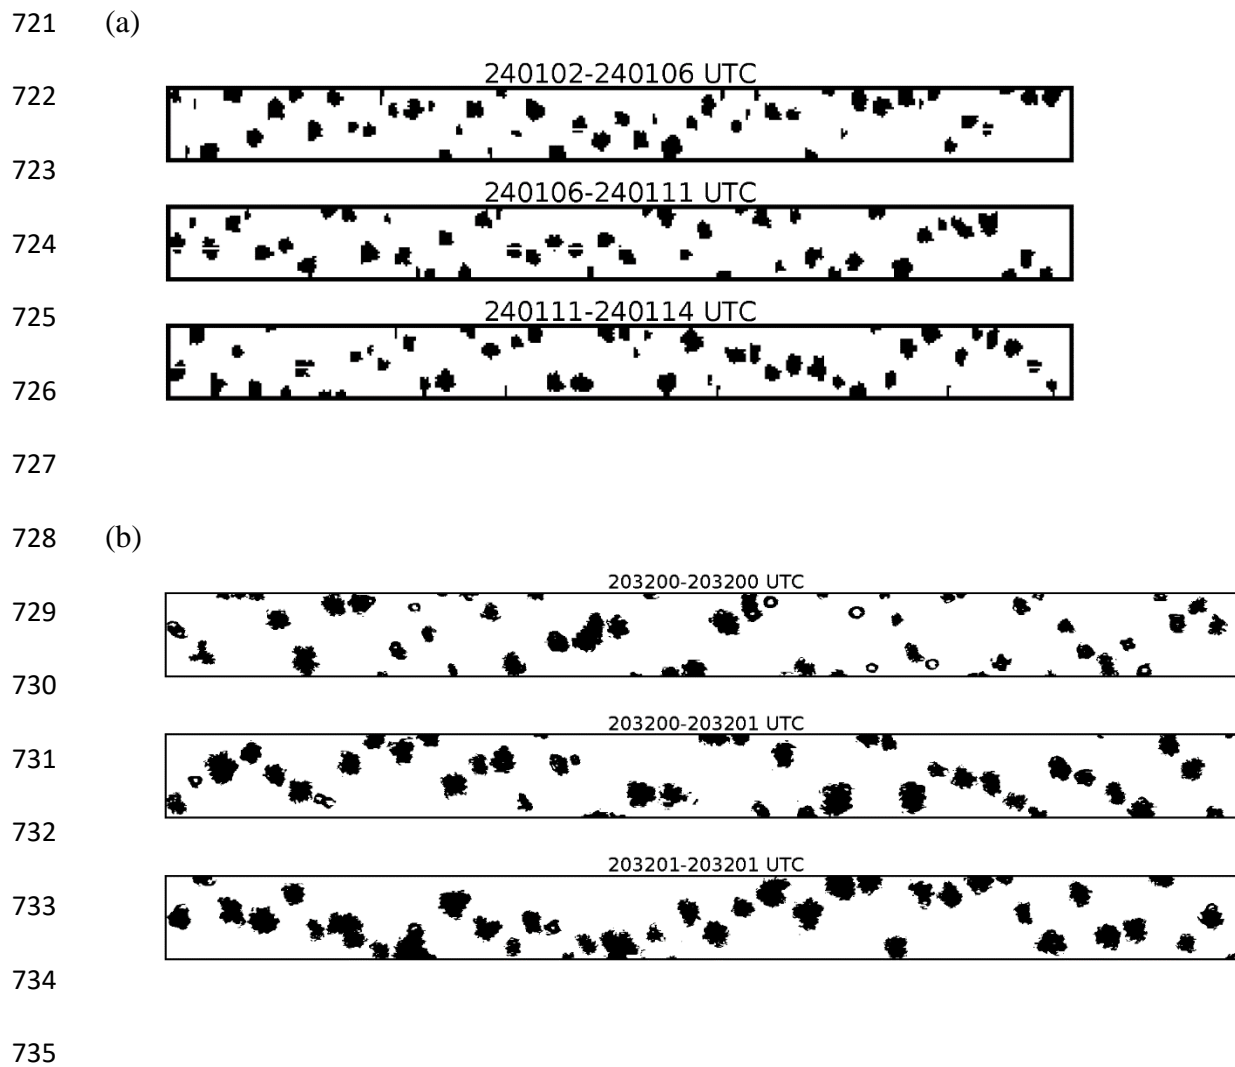

692 Particle images from 15 December 2016 were analyzed using the 2DP. With this
 693 instrument the maximum all-in particle size (in the horizontal direction perpendicular to flight) is

694 6400 μm and the particle size resolution is 200 μm (Sect. 2.2). Within the time interval picked
695 for this analysis (discussed below), particles sizing in the smaller of the two spectral modes, with
696 mode size $\sim 400 \mu\text{m}$, were more numerous (results not shown). Because the 400 μm particles are
697 poorly resolved by the 2DP, and the same can be said for somewhat larger particles, those
698 smaller than 1000 μm were excluded from the following analysis. Figure 11a shows imagery
699 from 12 s of measurements acquired near the end of the sequence in Fig. 9a (00:01:02 to
700 00:01:14). This time interval was selected by tracing forward from t_0 , along the slope of the fall
701 streaks, to the flight level. Many of the particles are rounded (indicating riming) and a few have
702 arms likely due to incomplete conversion of branched crystals to rimed snow particles. The mode
703 size corresponding to these images is 1600 μm . No liquid water was detected with these particles
704 ($\text{LWC} < 0.01 \times 10^{-3} \text{ kg m}^{-3}$; Fuller 2020; her Fig. 8), but liquid was detected, at $\sim 00:00:00$, as the
705 aircraft approached the ridgeline (Figs. 5a-b).

706 Turning to imagery from 3 January 2017, the most appropriate location for analysis
707 would be through the second billow structure evident in Fig. 10a. This billow sourced a fall
708 streak that terminated at the hotplate (i.e., at the time t_0 indicated in the figure). However, the
709 aircraft only clipped the top of this billow, and it was only when sampling the billow seen ~ 13 s
710 earlier that larger ice particle concentrations ($\sim 20,000 \text{ m}^{-3}$) (Fuller 2020; her Fig. 10) and larger
711 LWC ($\sim 0.08 \times 10^{-3} \text{ kg m}^{-3}$; Fig. 5d) were detected. Maximum reflectivities were the same in all
712 three billows ($Z \sim 1 \text{ mm}^6 \text{ m}^{-3}$; 0 dBZ), so it was assumed that imagery collected in the first
713 billow (20:32:00 to 20:32:02) was representative of what was falling toward the hotplate. The
714 2DS was used to image these particles (Fig. 11b); with this instrument the maximum all-in
715 particle size (in the horizontal direction perpendicular to flight) is 1280 μm and the size
716 resolution is 10 μm (Sect. 2.2). Most of the objects in Fig. 11b appear to be rimed and their mode

717 size is $\sim 400 \mu\text{m}$. It is also noted that particles smaller than $100 \mu\text{m}$ were eliminated from these
718 images, however, compared to the $\sim 400 \mu\text{m}$ particles those smaller than $100 \mu\text{m}$ were
719 significantly less abundant (results not shown).

720

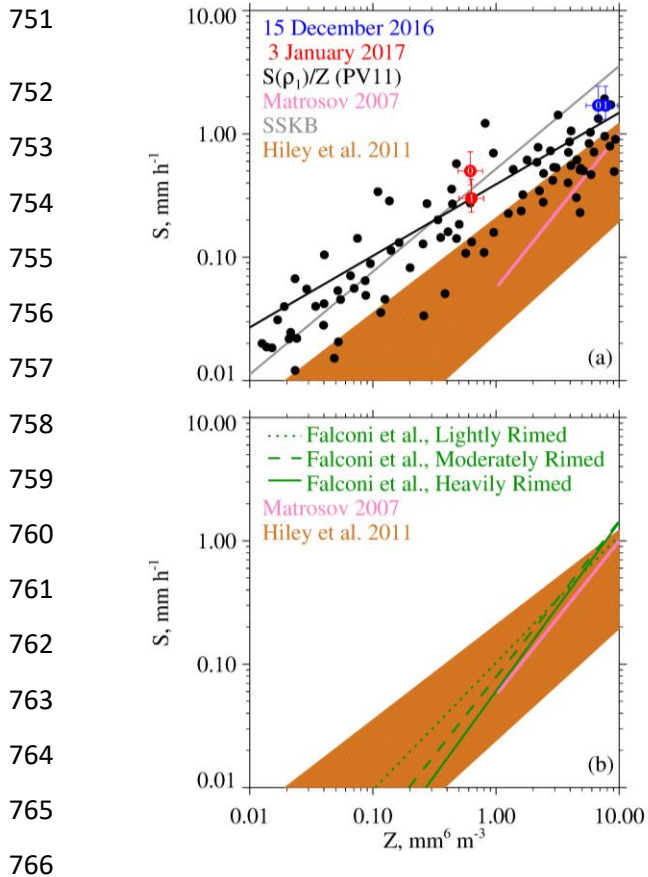

736 Figure 11 – (a) 2DP particle imagery from 15 December 2016. The height of the strips is 6400
737 μm . These particles are estimated to be representative of those that fell from flight level toward
738 the hotplate. (b) 2DS particle imagery from 3 January 2017. The height of the strips is 1280 μm .
739 These particles are estimated to be representative of those that fell from flight level toward the
740 hotplate.

741

742 3.7 – S/Z Relationships

743 Our S/Z pairs are presented in Table 5 where the indexes ($i = 0$ and $i = 1$) are used to
744 indicate results derived for the averaging intervals. In Table 5, reflectivities are not corrected for
745 attenuation, however, in Fig. 12a, attenuation-corrected reflectivities are plotted. Reflectivities
746 from Table 5, attenuations from Table 3, and Eq. 1 were used to calculate the corrected
747 reflectivities. Also shown is a subset of the S/Z pairs from PV11's Fig. 11 ($0.01 < Z < 10 \text{ mm}^6$
748 mm^{-3}) and the PV11 best-fit line (black). Results from PV11 are specified as $S(\rho_1)/Z$ because
749 those authors applied the lower of two density-size functions (ρ_1), and the lower of two fall
750 speed-size functions, with airborne measurements, in calculations of snowfall rates (Sect. 1).

768 Figure 12 – a) Snowfall rate versus radar reflectivity. Colored circles indicate attenuation-
 769 corrected reflectivities (Table 3, Table 5, and Eq. 1) for the $i = 0$ and $i = 1$ averaging intervals.
 770 Error bars on these points represent the precision of the Z measurement (Sect. 2.3) and the
 771 precision of the S measurement (Sect. 2.4). The $S(\rho_1)/Z$ points are a subset from PV11’s Fig. 11
 772 ($0.01 < Z < 10 \text{ mm}^6 \text{ mm}^{-3}$). Also plotted is the PV11 best-fit line (black) (Sect. 1), the S/Z
 773 relationship from Matrosov (2007) (Sect. 1), the S/Z relationship abbreviated SSKB (Sect. 1),
 774 and the swath of S/Z relationships from Hiley et al. (2011) (Sect. 1). b) S/Z relationships from
 775 Falconi et al. (2018) (their Table 2) (Sect. 1), the Matrosov (2007) relationship, and the swath of
 776 S/Z relationships from Hiley et al. (2011) are shown.

777

778 There are two potential biases in the values of S we measured (Table 5) and plot (Fig.
779 12a). First, the two snowfall events had flight-level vertical wind velocities that were positive
780 (upward) upwind of the summit, and vice versa downwind of the summit. Except for the
781 strongest downdraft on 3 January 2017, the magnitude of this variance is $\sim 1 \text{ m s}^{-1}$ (Figs. 5b and
782 5d). Assuming 1 m s^{-1} was the downward wind immediately over the hotplate, the snow particles
783 would have approached the gauge faster than their fall speed. Our basis for stating this is fall
784 speeds for the mode sizes discussed in Sect. 3.6 (1600 and $400 \mu\text{m}$) and our assumption that the
785 particles were graupel. (Table 6 has these characteristic sizes and fall speeds.) However, the
786 conjectured downdraft speed is likely an overestimate - because of divergence occurring as the
787 draft approached the surface - and because the sizes in Table 6 likely underestimate what fell to
788 the hotplate. Relevant to the last of these assertions, we used the altitude/T/RH measurements
789 (Table 2) to calculate the vertical distance available for growth via riming, and thus for a fall
790 speed increase, between the flight level and the lifted condensation level. Assuming an
791 adiabatically-stratified liquid cloud and unit collection efficiency (these assumptions
792 overestimate growth by riming), and no change of particle crosssection (underestimates growth by
793 riming), our calculations indicate that relative increases of size and fall speed were 40 and 20 %,
794 respectively, on 3 January 2017, and that these relative increases were a factor-of-two larger on
795 15 December 2016.

796

797 Table 6 – Estimates of snow particle fall speed

Date	Mode Size, μm	Assumed Particle Type	Fall Speed, m s^{-1}	Reference
15 December 2015	1600	graupel	1.4	PV11; assuming ρ_1 in their Fig. 5
3 January 2016	400	graupel	0.7	PV11; assuming ρ_1 in their Fig. 5

798

799

800 Second, there is concern that values of S from 3 January 2017 are underestimated.
801 Although values of S must be > 0 , we presented 1 Hz values (gray points, Fig. 8) approaching -
802 0.3 mm h^{-1} . Negative values resulted because we did not impose a threshold of 0 mm h^{-1} on the
803 uncorrected snowfall rates (this thresholding is discussed in Z18) and because negative snowfall
804 rate values (uncorrected for catch inefficiency) are amplified by the gauge-catch correction (Sect.
805 2.4). The implication is that 0.2 mm h^{-1} could be added to the one-minute averaged values of S in
806 Table 5 and in Fig. 12a. Here, the assumption is that an averaged S of -0.2 mm h^{-1} , in Fig. 8, is
807 indicating no snowfall at the hotplate; however, because the hotplate was operated autonomously
808 (Sect. 2.1) we have no way to verify the assumption.

809

810 4 – Results

811 Figure 12a shows the four S/Z pairs (red and blue circles, our measurements) after the
812 reflectivities were corrected for attenuation. The error bars on these data pairs represent the
813 precision of the Z measurement (Sect. 2.3) and the precision of the S measurement (Sect. 2.4).
814 Presentation clarity was what guided the selection of S and Z axis ranges in this figure but with
815 the consequence that 32 of PV11's S/Z pairs are not shown because they plot at $Z > 10 \text{ mm}^6 \text{ m}^{-3}$.
816 The way that the PV11 data pairs scatter closest to $Z = 10 \text{ mm}^6 \text{ m}^{-3}$, combined with the fact that
817 the PV11 data points at $Z > 10 \text{ mm}^6 \text{ m}^{-3}$ are not shown, could lead to the interpretation that the
818 slope describing the best-fit relationship at Z approximately $> 2 \text{ mm}^6 \text{ m}^{-3}$ should be decreased
819 relative to the slope of the PV11 best-fit line. Readers who view PV11's Fig. 11 will conclude
820 that this interpretation is not warranted. The four S/Z pairs (red and blue circles) plot above the
821 PV11 best-fit line but within the variability of PV11's S/Z pairs.

822 Computational S/Z relationship have inputs from parameterized descriptions of density,
823 shape, fall speed, PSD, and particle size (Sect. 1). Matrosov (2007) did calculations for the snow
824 particle type known as aggregates. Hiley et al. (2011) did calculations for 20 snow particle types.
825 Except for a S/Z calculation done for aggregate snowflakes, the calculations of Hiley et al.
826 (2011) were for the particle type known as vapor-grown crystals. Hiley et al. (2011) did not
827 model spherical snow particles. The latter were modeled by Surussavadee and Staelin (2007) and
828 Kulie and Bennartz (2009). In Fig. 12a, the abbreviation SSKB is used to symbolize the
829 computational S/Z relationship for spherical snow particles.

830 Fig. 12a shows the separation between our S/Z pairs and the Matrosov (2007) calculation.
831 The separation is about a factor of two for the points obtained on 15 December 2016. The points
832 obtained on 3 January 2017 plot at a Z smaller than the lower-limit of the calculation. Since the

833 particle images (Fig. 11a-b) reveal no evidence for the particle type modeled by Matrosov (2007)
834 (aggregate snowflakes), it is not surprising that the calculation is not representative of our
835 measurements.

836 Departures between our S measurements (Fig. 12a) and S/Z calculations from Hiley et al.
837 (2011) were evaluated as the vertical distance between the top of the orange region and our S/Z
838 data pairs. Snowfall rates at the top of the orange region were calculated using attenuation-
839 corrected reflectivities (Eq. 1 and Table 5) and using the upper-limit S/Z equation from Hiley et
840 al. (2011) ($S = 0.21 \cdot (Z')^{0.77}$; Sect. 1 and Eq. 1). The departures were evaluated as a relative
841 difference expressed as $(S_{HP} - S)/S$ with S_{HP} one of four snowfall rates from Table 5. The relative
842 difference is no smaller than 0.7 and 1.0 on 15 December and 3 January, respectively. These
843 minimum relative differences exceed the hotplate precision (Sect. 2.4) by at least a factor of two.
844 It is concluded that our paired values of surface-measured precipitation rate and aircraft-
845 measured radar reflectivity, after correcting for attenuation, provide evidence that a calculation
846 of S based on the Hiley et al. (2011) upper-limit, when applied to rimed snow particles, is
847 associated with a low-biased estimate of S.

848 A plausible explanation for the low bias is the smaller density implicit in most
849 computationally-based S/Z relationships and especially those which assume that snow particles
850 are crystals. Densities are quite different for crystals versus that for rimed snow particles. For
851 example, in Brown and Francis (1995), assuming a 2 mm crystal, the density is $\sim 30 \text{ kg m}^{-3}$,
852 whereas in PV11 (their Eq. 1), assuming a 2 mm graupel particle, the density is $\sim 200 \text{ kg m}^{-3}$.
853 Fig. 12a also has the SSKB relationship. This was developed using density = 200 kg m^{-3} (Sect. 1).

854 Compared to S/Z relationship represented by top of the orange region in Fig. 12a, the SSKB line
855 plots closer to our data points and closer to many of those reported by PV11.

856 Based on data from PV11 and our result, as well as the S/Z relationship abbreviated
857 SSKB (Sect. 1), it is expected that the S/Z relationships reported by Falconi et al. (2018) for
858 rimed snow particles (Sect. 1) would plot higher in S -versus- Z space than illustrated in Fig. 12b.
859 Notably, only the upper-end of the Falconi et al. lines ($Z > 8 \text{ mm}^6 \text{ m}^{-3}$) plot above the upper limit
860 that Hiley et al. (2011) established for unrimed snow particles. A plausible explanation for the
861 lower-than-expected S/Z relationships of Falconi et al. is now offered. Falconi et al. used liquid
862 water path as a proxy for the extent of snow particle riming (von Lerber et al. 2017). A
863 consequence may have been that the proxy did not dependably exclude unrimed snow particles
864 (crystals and aggregates) from the riming categories of Falconi et al. If this was true, then the
865 data groupings that were the basis for the Falconi et al. S/Z relationships may have been affected.
866 Further research is needed to resolve the reason for the mismatch between S/Z pairs, reported
867 both here and in PV11, and the S/Z relationships reported in Falconi et al.

868 Our conclusion that the upper-limit S/Z relationship from Hiley et al. (2011)
869 underestimates S would be modified if our WCR-derived reflectivities were negatively biased.
870 Assuming the reflectivities are negatively biased by 2.5 dBZ, the minimum relative differences
871 discussed previously are no smaller than 0.1 and 0.3 on 15 December and 3 January,
872 respectively. A bias in reflectivity of this magnitude cannot be ruled out but neither can a
873 positive bias of the same magnitude (Sect. 2.3). The latter increases the minimum relative
874 differences to 1.6 and 2.2 on 15 December and 3 January, respectively. In each of these
875 calculations we have summed the attenuations (Table 3) with ± 2.5 dBZ and used Eq. 1 to
876 calculate error-perturbed reflectivities.

877 The scatter of measurements in Fig. 12a, the plausibility of a -2.5 to +2.5 dBZ bias in
878 WCR reflectivity measurements, and error in measurement of S (Sect. 2.4), indicate that refined
879 techniques will be needed in future investigations which apply the approach described here.
880 Additionally, improved methods are needed to diagnose situations where riming is occurring
881 within clouds. Both lidars and radiometers can sense supercooled liquid water from space (e.g.,
882 Battaglia and Panegrossi, 2020), and if combined with Doppler radar, can diagnose precipitation
883 attributable to rimed snow particles. These approaches are being tested in ground-based field
884 studies (Kneifel et al. 2015; Moisseev et al. 2017; Mason et al. 2018) but are most reliable in
885 scenarios with the magnitude of vertical air speed smaller than particle fall speed.

886 **5 - Conclusions**

887 The reported measurements consist of surface measurements of S and near-surface
888 measurements of Z. The latter came from overflights of a ground site, where a precipitation
889 gauge was operated, and were acquired using an airborne W-band radar. The values of Z were
890 corrected for attenuation. The reported S/Z pairs plot at or above the S-versus-Z best-fit line of
891 PV11. However, the points do not depart beyond the variability evident in a replotting of S/Z
892 pairs from PV11. The PV11 data came from airborne measurements of W-band reflectivity,
893 acquired within ± 100 m of flight level, and from coincident measurements of snow particle
894 imagery. PV11 used a density-size function and a fall speed-size function, and measurements
895 (PSD and particle images) to calculate S.

896 There is an offset between the S points, reported here, and reflectivity-dependent S values
897 calculated at an upper-limit S/Z relationship for unrimed snow particles (Hiley et al. 2011). The
898 offset is larger than the precision of the S measurement. This suggests that a measured Z and the

899 Hiley et al. (2011) upper limit will produce an underestimate of precipitation in scenarios
900 dominated by rimed snow particles.

901 New research is needed to refine the S/Z relationship for rimed snow particles. This could
902 be computational – e.g., investigating the utility of parameterizing S in terms of both Z and
903 density – or could be observational. Unlike the investigation of PV11, where only an airborne
904 platform was employed, we have demonstrated that useful information can be obtained using
905 coordinated ground-based and airborne systems. Another approach would be with only ground-
906 based instrumentation. This would avoid some of the complications encountered in this study,
907 including W-band attenuation and a reliance on particle imagery acquired aloft. A study with
908 both ground-based and airborne systems would be useful for understanding a S/Z mismatch,
909 apparent at $Z < 8 \text{ mm}^6 \text{ m}^{-3}$, and which is larger than the offset summarized in the previous
910 paragraph. Elements of the mismatch are the S/Z measurements reported by PV11, the
911 measurements reported here, and the measurement-based S/Z relationships reported by Falconi et
912 al. (2018). These three research teams reported measurements relevant to the development of a
913 S/Z relationship for rimed snow particles.

914 **6 - Appendix**

915 This appendix explains how HP (hotplate) and WCR (Wyoming Cloud Radar) averages
916 were evaluated. The scheme starts with an HP averaging interval (duration 60 s) and derives a
917 WCR averaging interval and a WCR averaging domain. The latter encompasses a subset of the
918 altitude-time cross-section sampled by the WCR. The top boundary of the domain was derived
919 using vertical-component Doppler velocities within the interval/domain. Because of this
920 dependence, the line defining the top boundary had to be derived iteratively.

921 With the overflight time symbolized t_o , the beginning and ending times of the first of
 922 two 60-second HP averaging intervals are

$$923 \quad t_{HP,B} = t_o \quad (A1)$$

$$924 \quad t_{HP,E} = t_o + 60 \quad (A2)$$

925 Since two adjacent HP averaging intervals are evaluated in this analysis, we express the
 926 averaging times with the following recursive equations

$$927 \quad t_{HP,B}(i) = t_o + i \cdot 60 \quad (A3)$$

928 and

$$929 \quad t_{HP,E}(i) = t_o + (i+1) \cdot 60. \quad (A4)$$

930 In Eqs. A3-A4 the index is $i \in \{0, 1\}$. A special case with $i=2$ is also analyzed in Sect. 3.5,

931 Analogous to the recursion in Eq. A4, the ending time of a WCR averaging interval is

$$932 \quad t_{WCR,E}(i) = t_o - i \cdot 60 \cdot v_w / g_s. \quad (A5)$$

933 Here v_w is a wind advection speed (discussed below) and the second term on the rhs is a wind
 934 advection distance divided by the WKA (Wyoming King Air) ground speed (g_s). Analogous to
 935 the Eq. A5, the beginning time of a WCR averaging interval is

$$936 \quad t_{WCR,B}(i) = t_{WCR,E} - (i+1) \cdot 60 \cdot v_w / g_s \quad (A6)$$

937 The wind advection speed (v_w) in Eqs. A5-A6 was calculated using an altitude-
 938 dependent west-to-east wind velocity (u) and an altitude-dependent south-to-north wind
 939 velocity (v). These altitude-dependent component velocities were calculated using the
 940 horizontal wind vectors in the penultimate and last columns of Table 2. Plots of the component

941 velocities versus altitude and the linear functions used to relate component velocities to altitude
 942 are presented in Figs. A1a-b.

943 An altitude ($z' = 3400$ m) was assumed for evaluating the horizontal wind advection
 944 vector. This is the altitude of the ridges west and northwest of the HP site (Figs. 3a-b).

945 The WKA track vector (Table 2) defines the vertical plane of the WCR measurements.
 946 We assumed that wind advection of snow particles occurred parallel to this vector. With the
 947 assumption stated in the previous paragraph, the horizontal wind advection speed (v_w) was
 948 calculated as the projection of the horizontal wind vector onto the track vector.

$$949 \quad v_w = \frac{u(z') \cdot gs_x + v(z') \cdot gs_y}{(gs_x^2 + gs_y^2)^{1/2}} \quad (\text{A7})$$

950 In Eq. A7 the west-to-east and south-to-north components of the track vector are symbolized gs_x
 951 and gs_y . Vector representations of the track vector are in Table 2. On 14/15 December 2016 and
 952 3 January 2017, the values of v_w are 7.4 and 8.9 m s^{-1} , respectively.

953 In addition to the properties gs and v_w used to evaluate Eqs. A5-A6, a WCR averaging
 954 interval/domain was evaluated using a snow particle downward speed (Eq. A8).

$$955 \quad v_p = |\langle V_D \rangle| + \sigma_{V_D} \quad (\text{A8})$$

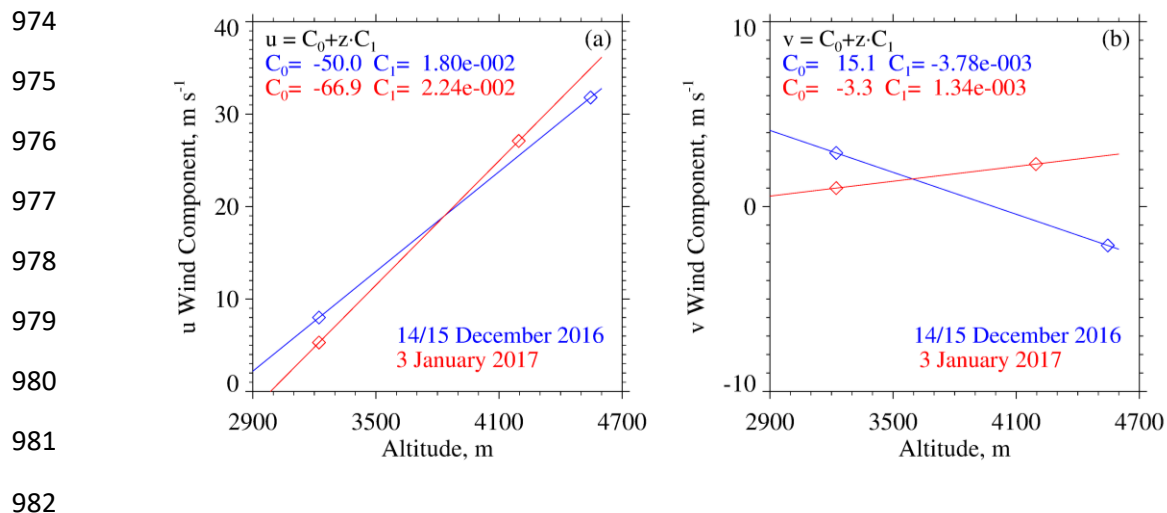

956 Here, $\langle V_D \rangle$ is the average of Doppler velocities within an averaging interval/domain, $|\langle V_D \rangle|$
 957 is the absolute value of the average, and σ_{V_D} is the standard deviation of the average. On both
 958 the lhs and rhs of Eq. A8, all terms are greater than zero.

959 We interpret v_p as the maximum likely snow particle speed toward the ground. There are
 960 three reasons for this: 1) For the WCR averaging intervals/domains we analyzed, values of

961 $\langle V_D \rangle$ were consistently less than zero (Table 5). This indicates that snow particles (on average)
962 were moving toward the ground. 2) Again, for the WCR averaging intervals/domains we
963 analyzed, σ_{V_D} was comparable to $|\langle V_D \rangle|$. This indicates that turbulent eddies transported snow
964 particles upward and downward at a speed comparable their downward speed in still air. 3) The
965 V_D are reflectivity weighted (Haimov and Rodi 2013) and are thus indicative of the motion of
966 the largest particles within an averaging interval/domain.

967 We now focus on the top boundary of a WCR averaging interval/domain. Figures 6b and
968 6d have representations of the boundary. The slope defining this boundary was calculated as
969 $-v_p \cdot g_s / v_w$. That is, particles below this boundary moved downward sufficiently fast and
970 horizontally sufficiently slow to advect reasonably close to the hotplate. Starting with diagnosed
971 values of g_s and v_w , the values of v_p and slope, were derived iteratively. The precision of the
972 derived v_p is $\pm 0.1 \text{ m s}^{-1}$.

973

983 Figure A1 – (a) West-to-east (u) wind velocity derived using measurements from the WKA and
 984 the AmeriFlux (AF) tower. Also shown is the linear function used to relate u to altitude. (b)
 985 South-to-north (v) wind velocity derived using measurements from the WKA and AF. Also
 986 shown is the linear function used to relate v to altitude. WKA and AF velocities are presented as
 987 vectors in the penultimate and last columns of Table 2.

988

989 Data Availability. The WKA and WCR measurements can be obtained from the SNOWIE data
990 archive of NCAR/EOL, which is sponsored by the National Science Foundation. Hotplate gauge
991 measurements are at <https://doi.org/10.15786/20103146>. The US-GLE AmeriFlux measurements
992 are at <https://ameriflux.lbl.gov/>. The Brooklyn Lake SNOTEL gauge measurements are at
993 <https://www.wcc.nrcs.usda.gov/snow/>. Merged Hotplate, SNOTEL, and AmeriFlux data
994 sequences from 14/15 December 2016 and 3 January 2017 are in Snider (2023).

995

996 Author contributions. JS and MB wrote the grant proposal that funded this research. Field
997 measurements were performed by SF, SM, SH, MB, and JS. SF wrote her MS dissertation, and
998 this was adapted for this paper by JS. KS processed the snow particle imagery. AM maintained
999 the measurement sites. All authors contributed to the editing of this paper.
