9 **Abstract**

10 Secondary organic aerosol (SOA) is a major fraction of the total organic aerosol (OA)
11 in the atmosphere. SOA is formed by the partitioning onto pre-existent particles of low
12 vapor pressure products of the oxidation of volatile, intermediate volatility, and
13 semivolatile organic compounds. Oxidation of the precursor molecules results in a
14 myriad of organic products making the detailed analysis of smog chamber experiments
15 difficult and the incorporation of the corresponding results into chemical transport
16 models (CTMs) challenging. The volatility basis set (VBS) is a framework that has
17 been designed to help bridge the gap between laboratory measurements and CTMs. The
18 parametrization of SOA formation for the VBS has been traditionally based on fitting
19 yield measurements of smog chamber experiments. To reduce the uncertainty of this
20 approach we developed an algorithm to estimate the SOA product volatility
21 distribution, effective vaporization enthalpy, and effective accommodation coefficient
22 combining SOA yield measurements with thermograms (from thermodenuders) and
23 areograms (from isothermal dilution chambers) from different experiments and
24 laboratories. The algorithm is evaluated with “pseudo-data” produced from the
25 simulation of the corresponding processes assuming SOA with known properties and
26 introducing experimental error. One of the novel features of our approach is that the
27 proposed algorithm estimates the uncertainty of the predicted yields for different
28 atmospheric conditions (temperature, SOA concentration levels, etc.). The predicted
29 yield uncertainty is significantly less than that of the estimated volatility distributions
30 for all conditions tested.

31

32 1. Introduction

33 Submicrometer atmospheric particles are of great importance due to their negative
34 effects on public health (Pope and Dockery, 2006; Lim et al., 2012) and their uncertain
35 influence on Earth's climate (IPCC, 2013). Organic aerosol (OA) contributes 20–90 %
36 to the submicron particulate mass (Zhang et al., 2007) and is emitted directly in the
37 atmosphere as primary particles (POA) or formed as secondary organic aerosol (SOA).
38 SOA constitutes a major fraction of the total OA in the atmosphere contributing more
39 than 60 % on average (Kanakidou et al., 2005). SOA is formed by the condensation of
40 low vapor pressure products of the oxidation of volatile (VOCs), intermediate volatility
41 (IVOCs), and semi-volatile organic compounds (SVOCs).

42 Hundreds of mostly unknown products are formed during the oxidation of each
43 SOA precursor making the detailed description of the corresponding reactions and
44 eventual SOA formation extremely challenging. The volatility basis set (VBS) is one
45 approach that has been proposed to simplify the system and to allow the SOA
46 simulation in CTMs. The VBS describes the volatility distribution of OA using a set of
47 surrogate species with effective saturation concentrations that vary by one order of
48 magnitude (Donahue et al., 2006; Stanier et al., 2008). Volatility is one of the most
49 important physical properties of SOA components as it determines to a large extent
50 their gas-particle partitioning (Pankow, 1994a; 1994b). The parametrization of SOA
51 formation for the VBS requires the determination of the yields of each volatility bin
52 (volatility distribution of products) and the corresponding enthalpies of vaporization.

53 The SOA parametrizations for the VBS have been traditionally based on fitting
54 yield measurements (Lane et al., 2008). The major weakness of this approach is that
55 the resulting parametrization is limited to the range of OA concentrations and
56 temperatures of the measurements. In most cases, the concentration range does not
57 include the low concentrations relevant to the atmosphere and usually most of the
58 experiments take place in a relatively narrow temperature range. Pathak et al. (2007a)
59 needed 37 smog chamber experiments at different temperatures (0–45 °C) and
60 atmospherically relevant concentrations to constrain the α -pinene SOA temperature
61 sensitivity.

62 A number of approaches has been used to minimize the number of experiments
63 needed to characterize the temperature dependence of the SOA formation. Stanier et al.
64 (2007) developed an experimental technique with which the temperature-controlled
65 smog chamber could be heated or cooled after the SOA formation moving the system

66 to new equilibrium favoring evaporation or condensation respectively. However,
67 interactions of the SOA with the walls of the system increased the uncertainties of the
68 approach. Stanier et al. (2008) presented an algorithm to fit the smog chamber
69 experiments using several volatility bins. However, the number of experiments needed
70 by the algorithm should cover a wide range of concentrations and temperatures to
71 effectively constrain the stoichiometric mass yields and the effective vaporization
72 enthalpy.

73 In an effort to cover a wider concentration and temperature range,
74 thermogravimetric measurements can be used. TD is a common instrument developed to
75 characterize the volatility of atmospheric aerosols by heating them and observing the
76 resulting changes in size, mass, optical properties, etc. (Burtscher et al., 2001; Wehner
77 et al., 2002, 2004; An et al., 2007). TDs consist of a heated tube in which the more
78 volatile particle components evaporate followed by a cooling section with activated
79 carbon to avoid vapor recondensation. The mass changes in TDs depend on the initial
80 SOA concentration, the residence time in the heating tube, the vaporization enthalpy,
81 and the mass transfer resistances. A typical way of reporting the TD measurements is
82 by calculating the aerosol mass fraction remaining (MFR) at a given temperature after
83 passing through the TD. The MFRs in a range of TD temperatures constitute the
84 thermogram.

85 In TD applications in the field (Cappa and Jimenez, 2010; Huffman et al., 2009;
86 Lee et al., 2010; Louvaris et al., 2017a) and in the laboratory (Kalberer et al., 2004;
87 Baltensperger et al., 2005; An et al., 2007; Lee et al., 2011; Cain et al., 2020) the system
88 does not reach equilibrium. Therefore, dynamic aerosol evaporation models (Riipinen
89 et al., 2010; Cappa, 2010; Fuentes and McFiggans, 2012) are needed for the
90 interpretation of TD measurements. Karnezi et al. (2014) used the time-dependent
91 evaporation model of Riipinen et al. (2010) to calculate the OA volatility distribution,
92 vaporization enthalpy, and mass accommodation coefficient from TD measurements.
93 The authors showed that a simple error minimization approach may not be appropriate
94 for such systems as very similar thermograms can be obtained for multiple
95 combinations of different parameters. For this reason, their approach estimates an
96 ensemble of “good” solutions, from which the best estimate and the corresponding
97 uncertainties are derived.

98 Grieshop et al. (2009) suggested the combination of TD and isothermal dilution
99 to constrain the volatility distribution of SOA. Karnezi et al. (2014) proposed an

100 algorithm to include both two types of measurements. The authors concluded that the
101 combination of the two type of measurements can better constrain the OA volatility
102 than each set separately. Louvaris et al. (2017b) and Cain et al. (2020) applied this
103 algorithm to cooking OA (COA) and SOA respectively. Louvaris et al. (2017b) showed
104 that the use of only TD measurements led to overestimation of the SVOC fraction of
105 COA, while the use of TD and isothermal dilution data reduces the uncertainty of the
106 volatility distribution and of the effective vaporization enthalpy. Cain et al. (2020)
107 obtained experimentally TD and isothermal dilution measurements for α -pinene and
108 cyclohexene ozonolysis SOA. The SOA in these two systems had similar thermograms,
109 but different areograms. When only thermograms were used in the model, the volatility
110 distributions were quite similar. However, the addition of areograms revealed that α -
111 pinene ozonolysis SOA consists mostly of LVOCs and the cyclohexene ozonolysis
112 SOA consists mostly of SVOCs.

113 To constrain the volatility product distribution of SOA and its effective
114 vaporization enthalpy we combine TD and isothermal dilution experiments with the
115 SOA yield measurements. We extend here the algorithm of Karnezi et al. (2014) by
116 introducing additional inputs (SOA yields) and also providing additional outputs
117 (uncertainty of estimated yields in relevant atmospheric conditions). The algorithm is
118 tested with “pseudo-experimental” data generated from the use of models simulating
119 the corresponding measurement processes, so the true parameters are known. The
120 results of the “pseudo-experiments” are corrupted so that they include experimental
121 errors.

122

123 2. Model Description

124 2.1. SOA Formation

125 Gas-phase oxidation of VOCs involves a large number of reactions and produces a large
126 number of products that can condense in the particulate phase. Depending on their
127 effective saturation concentration, they can be represented in the 1D-VBS framework
128 by

130 where n is the number of the surrogate compounds (volatility bins in the VBS), P_i is the
131 surrogate product in the i -th volatility bin and α_i is the corresponding stoichiometric
132 mass yield. The total SOA mass yield can be then calculated as:

133
$$Y \equiv \frac{C_{\text{OA}}}{\Delta\text{VOC}} = \sum_i^n \frac{\alpha_i}{1 + (C_i^*/C_{\text{OA}})} \quad (2)$$

134 where C_{OA} is the total SOA concentration, ΔVOC is the consumed concentration of the
135 VOC and C_i^* is the effective saturation concentration of compound i . This yield
136 equation is an extension of the two-product model by Odum et al. (1996) replacing their
137 semi-empirical partitioning coefficients with the assumption of a pseudo-ideal solution
138 (Strader et al., 1999). This model assumes that the system has reached equilibrium when
139 the yield was measured and that the differences in molecular weights are small.

140 The effective saturation concentrations at different temperatures are given by
141 the Clausius-Clapeyron equation:

142
$$C_i^*(T) = C_i^*(T_{\text{ref}}) \frac{T_{\text{ref}}}{T} \exp\left[\frac{\Delta H_{\text{vap},i}}{R} \left(\frac{1}{T_{\text{ref}}} - \frac{1}{T}\right)\right] \quad (3)$$

143 where T_{ref} is the reference temperature in which the reference effective saturation
144 concentration is defined (298 K in this work), and $\Delta H_{\text{vap},i}$ is the enthalpy of vaporization
145 of surrogate compound i .

146

147 2.2. Thermodynamic Model

148 The time-dependent evaporation of SOA in the TD is described in this work by the
149 dynamic mass transfer model of Riipinen et al. (2010). The evolution of the total
150 particle mass, m_p , and the gas phase concentration of the compound i , C_i are given by:

151
$$\frac{dm_p}{dt} = -\sum_{i=1}^n I_i \quad (4)$$

152
$$\frac{dC_i}{dt} = I_i N_{\text{tot}} \quad (5)$$

153 where n is the number of surrogate compounds, N_{tot} is the total number concentration
154 of particles (assuming monodisperse aerosol population) and I_i is the mass flux of
155 compound i from the gas to the particulate phase for each particle calculated by
156 (Seinfeld and Pandis, 2016):

157
$$I_i = \frac{2\pi d_p M_i \beta_{\text{mi}} D_i}{RT_{\text{TD}}} (p_i - p_i^0) \quad (6)$$

158 where d_p is the particle diameter, R is the ideal gas constant, M_i is the molecular weight
159 of compound i , D_i is the diffusion coefficient of compound i in the gas phase at
160 temperature T_{TD} , p_i and p_i^0 are the partial vapor pressures of i far away from the particle

161 and at particle surface, respectively, and β_{mi} is a factor for the correction of kinetic and
162 transition regime effects (Fuchs and Sutugin, 1970):

$$163 \quad \beta_{mi} = \frac{1 + Kn_i}{1 + \left(\frac{4}{3\alpha_{mi}} + 0.377 \right) Kn_i + \frac{4}{3\alpha_{mi}} Kn_i} \quad (7)$$

164 where Kn_i is the Knudsen number of compound i , and α_{mi} is the mass accommodation
165 coefficient of compound i on the particles. The partial vapor pressure of compound i at
166 the particle surface is given by:

$$167 \quad p_i^0 = x_{mi} \frac{C_i^* RT}{M_i} \exp\left(\frac{4M_i \sigma}{RT_{TD} \rho d_p} \right) \quad (8)$$

168 where x_{mi} is the mass fraction of compound i in the particulate phase, C_i^* is the effective
169 saturation concentration, σ is the surface tension (assumed 0.05 N m^{-1} in our
170 simulations), T_{TD} is the particle temperature assumed to be the same as in the TD, and
171 ρ is the particle density. The effective saturation concentrations at different TD
172 temperatures are given by Eq. (3).

173

174 2.3. Isothermal Dilution Model

175 In isothermal dilution experiments, a SOA sample is injected in a reactor filled with
176 clean air at room temperature. The concentrations of both the gas and particulate phase
177 components are lowered due to dilution leading the system out of equilibrium. The
178 evaporation of SOA as a result of isothermal dilution is also described by equations (3)-
179 (8) (Karnezi et al., 2014), but the temperature is equal to 298 K. Evaporation in a
180 dilution chamber depends on the initial SOA mass, time, and the α_m , but not on ΔH_{vap}
181 as the particles evaporate without a change in temperature.

182

183 3. Algorithm for the Estimation of VBS Parameters

184 The algorithm of Karnezi et al. (2014) was first extended to include an SOA partitioning
185 model together with the TD and isothermal dilution models in order to estimate the
186 volatility product distribution, vaporization enthalpy and accommodation coefficient.
187 We discretized the domain of the parameters and simulated all combinations of
188 stoichiometric mass yields (α_i), ΔH_{vap} , and α_m . The yields α_i were allowed to vary from
189 0.0 to 0.8, with values of 0.0, 0.05, 0.1, 0.15, 0.2, 0.3, 0.4, 0.6, and 0.8. Combinations
190 with sum of the yields exceeding 1.0 were excluded from the analysis. For a 4-product

191 system there are 3,153 and for a 6-product system 66,636 acceptable combinations. The
192 values used for ΔH_{vap} were from 20 to 200 kJ mol⁻¹ with a step of 20, and for α_m , the
193 values used were 0.001, 0.01, 0.1, and 1. As a result 126,120 simulations are needed
194 for a 4-product VBS and 2,665,440 for a 6-product solution.

195 For each simulation and each type of measurement, we calculated the
196 *normalized mean square error* (NMSE) defined as

$$197 \quad \text{NMSE} = \frac{\sum_{i=1}^{N_O} (P_i - O_i)^2}{\sum_{i=1}^n O_i} \quad (9)$$

198 where O_i represents the i th observed value (corresponding to a specific SOA
199 concentration for yield measurements or temperature for TD, or time for isothermal
200 dilution), P_i the corresponding model-predicted value, and N_O is the total number of
201 observations from each type of measurement. For each simulation (denoted as s), the
202 overall error was calculated by assuming equal weight to the set of yield, TD, and
203 dilution measurements and summing the corresponding errors:

$$204 \quad E_s = \text{NMSE}_{Y,s} + \text{NMSE}_{\text{TD},s} + \text{NMSE}_{\text{Dil},s} \quad (10)$$

205 The parameter combinations for which the overall error E_s is less than 5% are
206 identified. The best solution is then calculated by averaging these solutions using the
207 inverse error E_s as a weighting factor. The solutions that are closer to the measurements
208 have higher weight. More specifically the best estimate \bar{x} is given by:

$$209 \quad \bar{x} = \frac{\sum_k^N x_k \frac{1}{E_k}}{\sum_k^N \frac{1}{E_k}} \quad (11)$$

210 where x_k is the estimated value of a property (mass yield of a volatility bin, effective
211 vaporization enthalpy, or effective accommodation coefficient) and N is the number of
212 combinations with error below the threshold value. The uncertainty range of the
213 parameters is estimated by calculating the standard deviation (σ):

$$214 \quad \sigma = \sqrt{\frac{\sum_k^N \left[(x_k - \bar{x})^2 \cdot \frac{1}{E_k} \right]}{\sum_k^N \frac{1}{E_k}}} \quad (12)$$

215 following Karnezi et al. (2014).

216

217 4. Testing of the Algorithm

218 4.1. Generation of Data for Evaluation

219 In order to evaluate the algorithm, we generated data using the output of SOA
220 formation, thermodenuder and isothermal dilution models for systems with known
221 volatility distribution of the products, and properties. Then, these data were “corrupted”
222 with random errors to represent the “noise” observed in laboratory measurements for
223 yields, thermograms, and areograms. The yields were corrupted based on the variability
224 of laboratory measurements of Pathak et al. (2007a), by assuming a normal distribution
225 and standard deviation (σ_Y) given by:

$$226 \quad \sigma_Y = 0.1 Y_{\text{true}} + 0.02 \quad (13)$$

227 where Y_{true} are the correct yields.

228 For TD, the errors were calculated by assuming a normal distribution and the
229 standard deviation (σ_{TD}) suggested by Karnezi et al. (2014):

$$230 \quad \sigma_{\text{TD}} = 0.51 MFR_{\text{TD,true}} - 0.5 (MFR_{\text{TD,true}})^2 \quad (14)$$

231 where $MFR_{\text{TD,true}}$ are the correct MFR values for each TD temperature.

232 For dilution, the errors were calculated by assuming a uniform distribution and
233 standard deviation (σ_{Dil}) suggested by Karnezi et al. (2014):

$$234 \quad \sigma_{\text{Dil}} = 0.05 MFR_{\text{Dil,true}} + 0.03 \quad (15)$$

235 where $MFR_{\text{Dil,true}}$ are the correct MFR values for isothermal dilution.

236 Based on the above methodology, we generated “pseudo-measurements” of
237 yield, TD, and isothermal dilution for different SOA systems. The parameters used to
238 produce the pseudo-experimental data are summarized in Table S1. The “experimental”
239 conditions assumed for the TD and isothermal dilution measurements are shown in
240 Table S2.

241 In “Experiment” A, we test the performance of the algorithm against α -pinene
242 ozonolysis data and examine the effect of TD and isothermal dilution data. For
243 “Experiment” A, the “true” values were taken from the parameterization derived by
244 Pathak et al. (2007b) for the ozonolysis of α -pinene at low NO_x , dark and low RH
245 conditions. So these results are good fits of the measurements analyzed in that study.
246 The parametrization was derived assuming a 4-volatility bin system with saturation
247 concentrations ranging from 1 to $10^3 \mu\text{g m}^{-3}$. The effective vaporization enthalpy
248 estimated in that study was equal to 30 kJ mol^{-1} . Because the effective accommodation

249 coefficient was not part of the Pathak et al. (2007b) parametrization, we assumed a
250 value of 0.5 in this work. We used a small number of yield measurements at
251 atmospherically relevant SOA concentrations of 1, 5, 10, 20 and $40 \mu\text{g m}^{-3}$ (Fig. 1). For
252 this SOA system, the yield at $40 \mu\text{g m}^{-3}$ did not exceed 20%. The thermogram includes
253 ten MFR data points in the temperature range of 20 to 200 °C. For the highest
254 temperature, more than 70% of the SOA mass was evaporated. The areogram shows
255 that the correspondent SOA evaporated almost by 70 % in the first 0.5 h and more than
256 90% in less than 3 h.

257 For “Experiment” B, the “true” values were taken from the alternative
258 parametrization proposed by Pathak et al. (2007b) for the same oxidation system as
259 described before. This time, the authors used a 7-volatility bin system with saturation
260 concentrations ranging from 10^{-2} to $10^4 \mu\text{g m}^{-3}$ in their parametrization. The effective
261 vaporization enthalpy of the parametrization was 30 kJ mol^{-1} , while for the
262 accommodation coefficient we assumed again a value of 0.5. The yield, TD and
263 isothermal dilution “measurements” of Experiment B are generated in the same SOA
264 mass concentration, temperature, and dilution time range as in the previous pseudo-
265 experiment (Fig. 2).

266 For “Experiment” C, the “true” values were based on the parameterization of
267 the SOA formed during α -humulene ozonolysis by Sippial et al. (2022). The authors
268 measured high SOA yields for α -humulene in the main smog chamber ($\sim 70\%$ at $60 \mu\text{g}$
269 m^{-3}), and their corresponding thermogram suggested that the SOA particles fully
270 evaporated at 150 °C, while the areogram showed modest (20%) evaporation in the
271 dilution chamber after 3 hours. A 4-volatility bin set with saturation concentrations
272 ranging from 10^{-2} to $10 \mu\text{g m}^{-3}$ was used in that study to fit the measurements. The
273 stoichiometric coefficients of the three least volatile bins (10^{-2} , 10^{-1} and $1 \mu\text{g m}^{-3}$) were
274 around 0.1 and for the most volatile ($10 \mu\text{g m}^{-3}$) 0.25. The vaporization enthalpy was
275 115 kJ mol^{-1} and the accommodation coefficient was 0.01 (Table S1). We assumed five
276 yield “measurements” in the SOA concentration range of 1 to $100 \mu\text{g m}^{-3}$ with yield
277 values as high as 65 % at $100 \mu\text{g m}^{-3}$ (Fig. 3). The corresponding thermogram consisted
278 of 10 data and the particles fully evaporated at TD temperatures higher than 150 °C.
279 The areogram consisted of 17 data points and only 20 % of the SOA evaporated in the
280 dilution chamber.

281

282 4.2. Parameter Estimation for “Experiments” A, B, and C

283 We explored the performance of the algorithm for different choices of the number of
284 volatility bins, the range of saturation concentrations, and the range of SOA mass
285 concentration range in the yield measurements. For each test, the “true” and the
286 estimated properties are summarized in Table 1.

287 We evaluated the performance of our parameter estimation algorithm
288 comparing its predictions both against the “measurements” and also against the “truth”
289 defined as the predictions of the original parameterization. In both comparisons, *mean*
290 *normalized error* (MNE) (Emery et al., 2017) was used as metric.

291 For the evaluation against the “measurements”, the MNE_M was defined as

$$292 \quad MNE_M = \frac{100}{N_O} \sum_{i=1}^{N_O} \frac{|EST_i - O_i|}{O_i} \quad (16)$$

293 where EST_i is the estimated by the algorithm value and corresponds to a specific
294 measured point O_i .

295 For the evaluation against the “truth”, which includes conditions (e.g.,
296 temperatures or concentrations) for which there are no available measurements, the
297 MNE_T was defined as:

$$298 \quad MNE_T = \frac{100}{N_d} \sum_{j=1}^{N_d} \frac{|EST_j - TR_j|}{TR_j} \quad (17)$$

299 where EST and TR are the estimated and the “true” values respectively. N_d is the total
300 number of data points included in calculations and depends on the selected
301 discretization of the corresponding dependent variable (e.g., SOA concentration, TD
302 temperature, and dilution time). We used a linear discretization for the SOA
303 concentrations (from 0.01 to 50 $\mu\text{g m}^{-3}$ with a step of 0.01) and the TD temperatures
304 (20 to 200 °C with a step of 5 °C but including TD MFR values greater than zero). For
305 the dilution time, we used a higher resolution for the first 0.5 hour (step of 2 min), in
306 which the evaporation is usually faster, and lower then (step of 10 min) up to 3 hours.

307 Finally, we used the average relative standard deviation ($ARSD$) as a metric to
308 quantify the uncertainty of the estimates (range of good solutions) using the same
309 discretization as in the MNE_T metric. The $ARSD$ is given by:

$$310 \quad ARSD = \frac{100}{N_d} \sum_{j=1}^{N_d} \frac{\sigma_j}{EST_j} \quad (18)$$

311 where σ_j is the standard deviation for data point j .

312 4.2.1 Parameter Estimation for “Experiment” A

313 In Test A1, we applied the algorithm in the same range of saturation concentrations and
314 with the same number of volatility bins as these used to produce the “experimental”
315 data. The upper bin ($10^3 \mu\text{g m}^{-3}$) exceeded the maximum SOA concentration ($40 \mu\text{g}$
316 m^{-3}) in the measurement range by one order of magnitude.

317 Figure 1 depicts the estimated and the range of the ensemble of best solutions
318 for the three types of “measurements” for Test A1. The performance of the model for
319 the yields at 25°C was quite encouraging with a small tendency of overprediction for
320 SOA higher than $10 \mu\text{g m}^{-3}$. The MNE_M of the model for the SOA yield “measurements”
321 (given by Eq. 16) was equal to 25% (Table 2). The corresponding discrepancy between
322 the true parameterization and the measurements (due to the measurement error that we
323 introduced) was 21.2% (Table 2). This indicates that a significant part of the algorithm
324 error can be explained by the uncertainty introduced in the measurements.

325 Our algorithm can be used to calculate the SOA yield at different concentrations
326 and temperatures. The yields were calculated in the atmospherically relevant range of
327 $0\text{--}50 \mu\text{g m}^{-3}$ SOA concentration and at four temperatures (5, 15, 25, and 35°C) using
328 the true parameter values and the estimated parameters of Test A1. At 25°C , the
329 estimated yield curve is in good agreement with the “true” yield curve for SOA
330 concentrations lower than $6 \mu\text{g m}^{-3}$ (error of 8% at $6 \mu\text{g m}^{-3}$), but the discrepancies
331 increase at higher concentrations (error of 23% at $50 \mu\text{g m}^{-3}$). The average MNE_T error
332 between the true parametrization and the estimated values (given by Eq. 17) was equal
333 to 17.3% for yields at 25°C (Table 3). The uncertainties, as expected, are larger at lower
334 temperatures. However, the MNE_T error (estimated yields compared to the true value)
335 remains less than 25% (Table 3) even at 5°C , quite far from the measurement
336 temperature.

337 The algorithm provides a range of “good” estimates in addition to the best
338 estimate. The range can be defined by the lower and upper SOA yield limits of the
339 ensemble of the good solutions at each point. At 25°C , the yield range increased, as
340 expected, at higher concentrations (yield range of 0.05 at $1 \mu\text{g m}^{-3}$ to 0.17 at $50 \mu\text{g}$
341 m^{-3}). The average relative standard deviation ($ARSD$ of the estimated yields defined by
342 Eq. 18) was equal to 26% (Table 4) for the 25°C case. For the rest of the temperatures,
343 the $ARSD$ increased for the lower temperatures, ranging from 24% at 35°C to 35% at
344 5°C (Table 4) and including in all cases the true solution.

345 For the TD, the model reproduced well the correspondent thermogram with low
346 errors compared to the “measurements” with an error MNE_M of 7% (Table 2). The error
347 MNE_T compared to the “true” values was 5.5% (Table 3). The error of the TD
348 “measurements” compared to the true values was equal to 7.6% (Table 2). Therefore,
349 the error of the proposed algorithm is quite similar to the experimental error. The error
350 introduced into the “measurements” was transferred, as expected, to the error metrics
351 of the algorithm.

352 For the isothermal dilution, the algorithm did reasonably well for the first 30
353 minutes and then the evaporation was slightly underpredicted leading to an error MNE_M
354 of 16.7% (Table 2). This MNE_M value was roughly two times higher than the
355 corresponding error between the dilution measurements and the true parametrization
356 (Table 2). The error between the estimated and the “true” values MNE_T was 19%. The
357 $ARSD$ of 24% (Table 4) was sufficient to include the true solution.

358 The estimated volatility distribution of the products and the effective
359 vaporization enthalpy and accommodation coefficient using the three types of
360 measurements can be seen in Figure 4 and Table 1. The estimated volatility distribution
361 of the products was in a good agreement with the “true” values (α_i absolute difference
362 of 0.01 at $1 \mu\text{g m}^{-3}$, 0.03 at $10 \mu\text{g m}^{-3}$, 0.07 at $10^2 \mu\text{g m}^{-3}$, and 0.04 at $10^3 \mu\text{g m}^{-3}$) and
363 the estimated uncertainties contained the correct values. There is a large uncertainty
364 range for the two higher volatility bins (standard deviation higher than 0.13) indicating
365 that yield values at a wider range of SOA concentrations would be needed to better
366 constrain these volatility bins. The relative error of the estimated ΔH_{vap} is 10%. The
367 estimated accommodation coefficient was 0.17 compared to a true value of 0.5. The
368 estimated uncertainty for the effective accommodation was almost one order of
369 magnitude (from 0.06 to 0.51) indicating the difficulty of constraining this parameter
370 when it is close to unity and thus the resistances to mass transfer are small.

371

372 4.2.2 Parameter Estimation for “Experiment” B

373 In this section, we used the pseudo-experimental data of Experiment B, which were
374 obtained for an SOA system with more components and a much wider range of
375 volatilities including LVOCs, SVOCs and IVOCs (10^{-2} – $10^4 \mu\text{g m}^{-3}$). In Test B1, the
376 algorithm was applied using a 4-bin VBS with saturation concentrations ranging from
377 1 to $10^3 \mu\text{g m}^{-3}$. This range is narrower than the actual range used to obtain the pseudo
378 measurements of Experiment B.

379 Figure 2 shows the results of the fitting for the three types of “measurements”
380 in this experiment. At 25 °C, the model performance for the yields is encouraging
381 ($MNE_M=20.6\%$). This is again pretty close to the measurement error (20.5%). By
382 comparing the estimated and the “true” yield curves at 25 °C, the error MNE_T is now
383 14%. The error increases to 31% at 5 °C, far from the available measurements. This is
384 reflected also in the increase of the uncertainty of our estimates with the $ARSD$
385 increasing from 17% at 35 °C to 37% at 5 °C (Table 4). Once more the uncertainty
386 range estimated by the algorithm includes the true values.

387 Both “measured” and “true” thermogram were well captured by the best
388 estimate (MNE_M of 6% and MNE_T of 4%) with an uncertainty $ARSD$ of 20.5%. The
389 evaporation in the dilution chamber was a little underestimated for the first 2 h, but then
390 it was slightly overpredicted. The MNE_T for the areogram was 13.3% and the true values
391 were included within the range of the estimates ($ARSD$ of 18%).

392 Figure 5 shows the results of Test B1 for the volatility distribution of the
393 products. The “true” stoichiometric coefficient for the $1 \mu\text{g m}^{-3}$ bin was overestimated
394 by 0.01 by the algorithm. This overestimation actually corresponds to the total material
395 of the 10^{-2} and $10^{-1} \mu\text{g m}^{-3}$ bins of the “true” system. This indicates that the algorithm
396 places the material of the two lowest bins that are not part of the solution to the bin with
397 the lower volatility. For the $10 \mu\text{g m}^{-3}$ and $10^2 \mu\text{g m}^{-3}$ bins, the relative errors between
398 the estimated and “true” were 58% and 277% respectively (Table S3), while for the 10^3
399 $\mu\text{g m}^{-3}$ bin, the relative error was 10 %. The ΔH_{vap} was predicted accurately (error of
400 only 4%), while α_m was underpredicted (0.1 instead of 0.5).

401 The results of Test B1 suggest that the mismatch between the actual SOA
402 volatility distribution and the range used for the fits can introduce significant errors in
403 the retrieved distribution for individual volatility bins. However, despite these problems
404 the yields predicted by the derived parameterizations have a much lower error than the
405 volatility distribution. This is a valuable insight for the strengths and weaknesses of this
406 and other similar SOA parameter estimation algorithms.

407

408 **4.2.3 Parameter Estimation for “Experiment” C**

409 In Test C1, we obtained the best fits for the pseudo-measurements of Experiment C by
410 applying the algorithm in the same range of saturation concentrations and with the same
411 number of volatility bins (4 volatility bins in the 10^{-2} – $10^1 \mu\text{g m}^{-3}$ saturation
412 concentration range) as the true volatility distribution.

413 Figure 3 shows the results of the fitting for the three types of “measurements”.
414 The best estimate for the SOA yields at 25 °C was in a good agreement with the
415 “measurements” ($MNE_M=6.3\%$) and the “true” values ($MNE_T=9.6\%$). For the rest of
416 the temperatures, there was a decreasing trend of the error as the temperature decreased
417 varying from 15.5% at 35 °C to 6.2% at 5 °C. A similar decreasing trend was observed
418 for the uncertainty $ARSD$ of the estimates which varied from 23% at 35 °C to 15% at 5
419 °C. This behavior is the opposite from what we observed in the previous tests, in which
420 both errors and uncertainties increased at lower temperatures. However, the changes in
421 both the error and the uncertainty are small (change of around 7% between the upper
422 and lower temperature for both metrics), indicating that this system is less temperature-
423 sensitive in this temperature range than the previous ones.

424 The performance of the algorithm was satisfactory compared to the TD
425 “measurements” ($MNE_M=12.9\%$). The corresponding error of the algorithm for the true
426 values (MNE_T) was 4.4% for temperatures up to 110 °C and equal to 10.6% for the
427 lower values at higher temperatures. According to Figure 3, the evaporation due to
428 dilution was initially overestimated for the first 30 min, but then underestimated
429 (highest MFR discrepancy of 0.05) and there is a high uncertainty range of the
430 corresponding estimates (MFR range of 0.46 at 3 h). However, the low dilution values
431 resulted in low relative errors (MNE_M of 3.5% and MNE_T of 2.7%).

432 Figure 6 shows that the highest relative errors were calculated for the 10^{-1} and
433 $10^0 \mu\text{g m}^{-3}$ bins (23% and 33% respectively), and smaller relative errors for the other
434 two bins (less than 13%). The uncertainties were almost of the same magnitude for all
435 bins with standard deviations ranging from 0.09 to 0.13. The performance of the model
436 was good for the ΔH_{vap} (relative error of 7%), but with high uncertainty for α_m .

437

438 4.3. Effect of the Volatility Range

439 In in this section, we explore the performance of the algorithm for different choices of
440 the number of volatility bins and the range of saturation concentrations. The analysis
441 of the results of Test B1 has already quantified the effects of using a narrower volatility
442 distribution in the parameter estimation algorithm than the one of the investigated SOA
443 system. Additional sensitivity tests are performed here for all cases.

444 In Test A2, we used 3 volatility bins covering the $1\text{--}10^2 \mu\text{g m}^{-3}$ saturation
445 concentration range instead of the 4 bins used in Test A1 and covering the $10^3 \mu\text{g m}^{-3}$
446 material. The narrower assumed volatility range had a very small effect on the estimated

447 yields at all temperatures (Table 3 and Fig. S1) compared to Test A1. The change in
448 MNE_T ranged from 3% at 5 °C to 0.3% at 35 °C. Minor changes were detected in the
449 predicted thermogram (change of 0.8%) and areogram (change of 0.5%) as well. The
450 uncertainty of the yield estimates increased by less than 2.5% at all temperatures. The
451 estimated volatility distribution of the SOA products of Test A2 changed by less than
452 5% in the two lower bins. The material in the $10^2 \mu\text{g m}^{-3}$ increased by 15% to account
453 for the SOA of higher volatility that could not be included otherwise in the estimated
454 distribution. The estimated ΔH_{vap} was in this case 32 kJ mol^{-1} (2.7% decrease) and the
455 α_m decreased by 12% with respect to Test A1.

456 In Test A3, we shifted the assumed 4-bin volatility distribution by one order of
457 magnitude to lower values, covering in that way the 0.1–100 $\mu\text{g m}^{-3}$ saturation
458 concentration range. In this case, the algorithm distributed exactly the same material to
459 the 1, 10 and 100 $\mu\text{g m}^{-3}$ volatility bins as in Test A2, and it predicted correctly zero
460 SOA in the 0.1 $\mu\text{g m}^{-3}$ bin (Table 1). The ΔH_{vap} and α_m estimated values were also
461 unchanged with respect to Test A2. This in turn, led to the same estimated yields at
462 different temperatures (no change in the error between the two tests).

463 In Test C2, we applied the algorithm against the Experiment C “measurements”
464 using a 4-volatility bin system in the 1 to $10^3 \mu\text{g m}^{-3}$ range, that is two orders of
465 magnitude higher than the actual range of the “true” values. Figure 7 shows the results
466 of the fitting for the three types of “measurements”. Despite the significant mismatch
467 of the volatility distributions the MNE_M increased by only 2.3% for the estimated SOA
468 yields. The error for the TD measurements increased by 20% while it actually decreased
469 a little (1.2%) for the dilution data. The errors compared to the true values increased by
470 less than 3% for the temperature range 15–35 °C while it increased by 12% at 5 °C.
471 These results suggest that the estimated yields are quite robust in this case to the
472 assumed volatility range. The major effect of the mismatch in volatility ranges was
473 evident in the predicted thermogram with overestimation of the MFR for the 60–120
474 °C temperature range and underprediction in higher temperatures. The increase in
475 MNE_T for the TD MFR was 17.2% (Table 3). The change in the predicted areogram
476 was marginal and led to a small increase of MNE_T (error increase by 0.7%) (Table 3).
477 The algorithm underestimated again the α_m (0.004 instead of 0.01) but also recognized
478 the high uncertainty of the corresponding estimate. The algorithm distributed
479 significant material to the 1 $\mu\text{g m}^{-3}$ bin (3.6 times higher than the actual), in an effort to

480 account for the absence of the 10^{-2} and 10^{-1} $\mu\text{g m}^{-3}$ bins. The ΔH_{vap} was underestimated
481 with an error of 21%.

482 The results of the above tests indicate that a mismatch between the true and
483 assumed volatility ranges of the SOA increases in general the estimation error but the
484 increase is small to modest. This is reassuring for the robustness of the proposed
485 algorithm.

486

487 **4.4. Effect of Measurements at high SOA Levels**

488 During the last decade there has been a significant shift of the performed SOA smog
489 chamber towards lower SOA concentrations. This is needed to increase the accuracy at
490 the ambient concentration levels. The high SOA concentration experiments that once
491 represented the majority of the performed experiments are becoming increasingly rare.
492 In this paragraph we examine the value of these high concentration experiments for the
493 estimation of SOA yields at ambient conditions.

494 To examine the effect of “measurements” at SOA levels much higher than the
495 atmospheric ones, we included an extra yield measurement at $200 \mu\text{g m}^{-3}$ in the yield
496 data of Experiments A and B. In Test A4 and B2, we applied the algorithm once again
497 against the three types of “measurements” by using a 4-volatility bin system with
498 saturation concentrations ranging from 1 to $10^3 \mu\text{g m}^{-3}$.

499 In Test A4, the additional experiment at high SOA concentration led to an MNE_T
500 of 15.7% for the yields at 25°C (Table 3 and Fig. S2), which is by 1.6% lower than that
501 without this experiment in Test A1. The improvement was more significant at lower
502 temperatures e.g., the MNE_T at 5°C was reduced from 24.4% to 20.4%. The reduction
503 in the $ARSD$ for the SOA yields ranged from 3.8% at 5°C to 0.9% at 35°C (Table 4).
504 Figure 8 depicts the results of the model for the yields and the volatility distribution of
505 the products for Test A4. The accuracy of the predicted volatility distribution increased
506 especially for the higher volatility material. For example, the error for the $10^2 \mu\text{g m}^{-3}$
507 bin was reduced from 41% in Test A1 to 6% in this case (Table S3). Minor changes in
508 the errors were detected for the ΔH_{vap} and α_m between the two tests (3% increase and
509 6% decrease respectively).

510 Similar to Test A4, in Test B2 we added a yield measurement at $200 \mu\text{g m}^{-3}$ in
511 the Experiment B set of “measurements”. Figure 9 depicts the results of the model for
512 the SOA yields at 25°C and the estimated volatility distribution of the products. The
513 use of the additional data point led to a reduction of the NME_T from 13.9% in Test B1

514 to 9% in Test B2 at 25 °C (Table 3). Similar reductions in the NME_T were observed for
515 the other temperatures, with the highest one observed at 5 °C (lower error by 7%)
516 (Figure 10). The reduction in the $ARSD$ for the estimated yields ranged from 3.3% at 5
517 °C to 1.2% at 35 °C (Table 4). Minor changes were observed for the estimated
518 thermogram (Fig. S3) (change in the NME_T of 1.5%) and the uncertainty of the
519 estimates (change in the $ARSD$ of 2.5%). The error in the estimated areogram was also
520 small but in this case the error increased by 5%. The additional data point helped
521 decrease the errors for the estimated mass of the more volatile SOA products (Fig. 9)
522 and especially for the $10^2 \mu\text{g m}^{-3}$ bin. The ΔH_{vap} and α_m estimated values were only
523 slightly affected by the additional measurement.

524 These results suggest that an additional yield measurement at high SOA can
525 lead to a substantial reduction of the error for the estimated yields at low temperatures
526 (Fig. 10) and also a better estimation of the SOA products with higher volatility (10^2
527 and $10^3 \mu\text{g m}^{-3}$). These products may contribute little to the SOA concentration at 25
528 °C, but their reactions (aging) could lead to significant additional SOA in later stages.
529

530 5. Conclusions

531 An algorithm was developed to estimate VBS parameters for SOA formation
532 combining yield measurements from atmospheric simulation chambers with
533 thermodenuder and isothermal dilution measurements chambers. An additional feature
534 of this approach is that the algorithm estimates the uncertainty of the predicted SOA
535 yields for different SOA concentrations and temperatures, assisting in this way in the
536 design of future experiments.

537 The algorithm was evaluated against pseudo-experimental data for SOA
538 systems with known properties. The algorithm performed quite well at reproducing the
539 SOA yields at atmospherically relevant concentrations and temperatures with errors
540 less than 20% for practically all cases. This was the case even at temperatures as low
541 as 5 °C and also when the volatility range used for the parameter estimation was
542 narrower than that of the simulated SOA system. One should note that this error was
543 quite similar in most cases to the experimental error assumed in the construction of the
544 “measurement” datasets.

545 The errors in the retrieved SOA volatility distributions were in general higher
546 than those of the SOA yields. This is due to a large extent to the existence of multiple

547 solutions that can result in similar yields. The accuracy of the estimated mass fractions
548 of the more volatile SOA components improved when an additional yield measurement
549 at high SOA (e.g., at $200 \mu\text{g m}^{-3}$). The addition of this measurement also improved the
550 estimated yields at low temperatures. This therefore suggests that data points at high
551 SOA concentrations should also be obtained experimentally, together with the data
552 points at atmospherically relevant atmospheric SOA levels.

553 In all cases the algorithm results in good estimates of the effective evaporation
554 enthalpy. On the other hand, the estimates of the effective accommodation coefficient
555 are usually quite uncertain.

556 The approach combining yield, TD (thermograms), and isothermal dilution
557 (areograms) measurements is recommended for future parametrizations of SOA
558 formation.

559

560 **6. Code and data availability**

561 The code and simulation results are available upon request
562 (spyros@chemeng.upatras.gr).

563

564 **7. Supplementary information**

565

566 **8. Author contribution**

567 PU, and SNP designed the research. PU developed the final model code. AD developed
568 a first version of the code and performed preliminary feasibility tests. DS and SNP
569 designed the experiments for the α -humulene ozonolysis and DS carried them out. PU
570 performed the simulations, the formal analysis, and wrote the original draft. Paper
571 review and editing was performed by SNP.

572

573 **9. Competing interests**

574 The authors declare that they have no conflict of interest.

575

576 **10. Financial support**

577 This work has been supported by the Chemical evolution of gas and particulate-phase
578 organic pollutants in the atmosphere (CHEVOPIN) Project of the Hellenic Foundation
579 for Research and Innovation (HFRI) under grant agreement no. 1819 and the European

580 Union's Horizon 2020 research and innovation program through the EUROCHAMP-
581 2020 Infrastructure Activity under grant agreement no. 730997.

Table 2: The *mean normalized error* (MNE) between the “measurements” and “true” values, and between the “measurements” and the model estimated values for the different tests.

Test	“Measurements” vs “True” ^a			“Measurements” vs Estimated <i>MNE_M</i> ^b		
	Yield	TD	Dilution	Yield	TD	Dilution
A1	21.2	7.6	9.4	25.0	7.0	16.69
A2	21.2	7.6	9.4	25.1	7.1	16.71
A3	21.2	7.6	9.4	25.1	7.1	16.71
A4	17.8	7.6	9.4	22.4	7.1	19.7
B1	20.5	6.9	5.6	20.6	6.0	14.7
B2	18.1	6.9	5.6	19.1	7.8	18.1
C1	8.4	11.6	1.8	6.3	12.9	3.5
C2	8.4	11.6	1.8	8.6	32.4	2.3

^a Calculated by $\frac{100}{N_o} \sum_{i=1}^{N_o} \frac{|O_i - TR_i|}{O_i}$.

^b Calculated by Eq. (16).

Table 3: The mean normalized error between the “true” and estimated values (MNE_T) for the different tests.

Test	Yield				TD	Dilution
	5 °C	15 °C	25 °C	35 °C		
A1	24.4	21.0	17.3	13.8	5.5	19.0
A2	21.4	19.5	16.9	14.1	4.7	18.5
A3	21.4	19.5	16.9	14.1	4.7	18.5
A4	20.4	18.3	15.7	12.9	6.0	22.5
B1	31.3	21.7	13.9	8.7	4.0	13.3
B2	24.4	15.6	9.0	6.4	2.5	18.4
C1	6.2	6.8	9.6	15.5	4.4 (110 °C)* 10.6 (140 °C)*	2.7
C2	18.1	9.6	7.2	11.5	9.0 (110 °C)* 27.8 (140 °C)*	3.4

* The errors for TD were calculated up to the denoted temperature in the parenthesis.

Table 4: The average relative standard deviation ($ARSD$) for the different tests.

Test	Yield				TD	Dilution
	5 °C	15 °C	25 °C	35 °C		
A1	34.6	29.7	26.0	24.2	21.0	23.6
A2	32.1	28.5	25.2	23.3	21.1	23.2
A3	32.1	28.5	25.2	23.3	21.1	23.2
A4	30.8	27.2	24.5	23.3	21.0	22.1
B1	37.1	27.2	20.0	16.9	20.5	18.0
B2	33.8	25.0	18.5	15.7	18.0	15.9
C1	15.0	14.9	16.2	22.9	20.7*	16.5
C2	20.1	15.6	14.1	21.3	20.6*	9.8

* The $ARSD$ for the TD MFR values were calculated in the 20–120 °C temperature range.

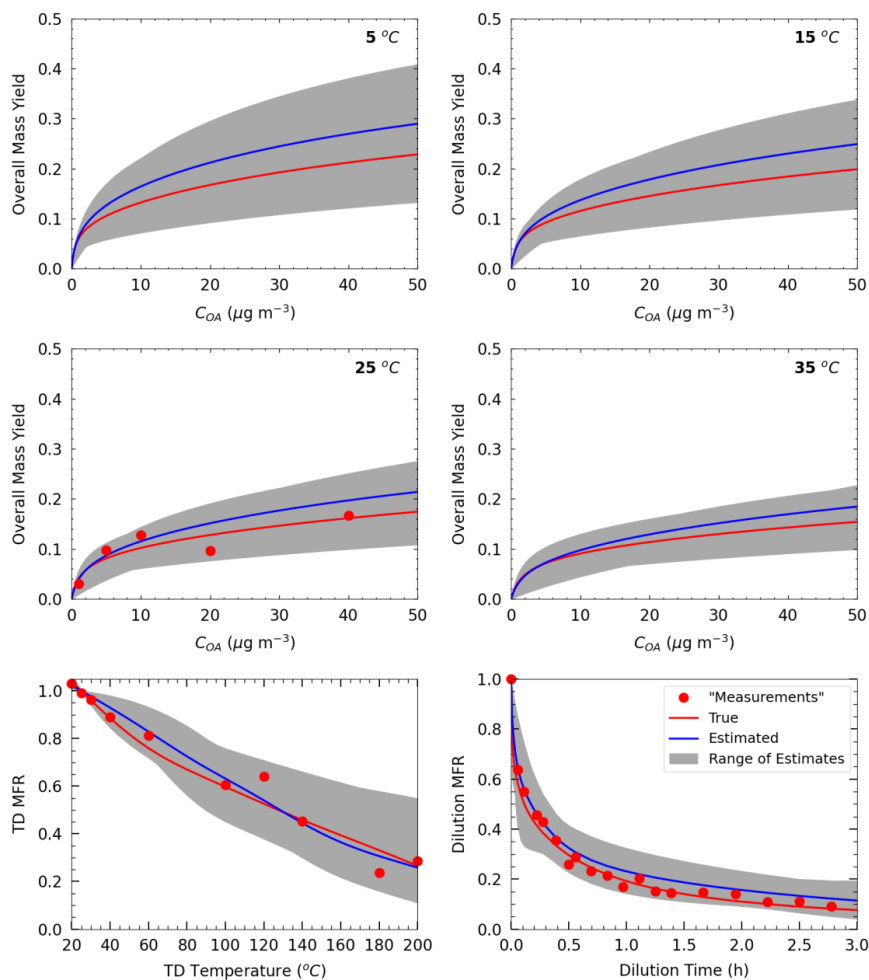

Figure 1: “Measurements” of Test A1 in Experiment A (red dots), true (red line) and estimated (blue line) yields at four temperatures (at 5 °C, 15 °C, 25 °C, and 35 °C), TD (thermogram), and dilution (areogram) values. The grey area shows the range of good solutions obtained by our algorithm.

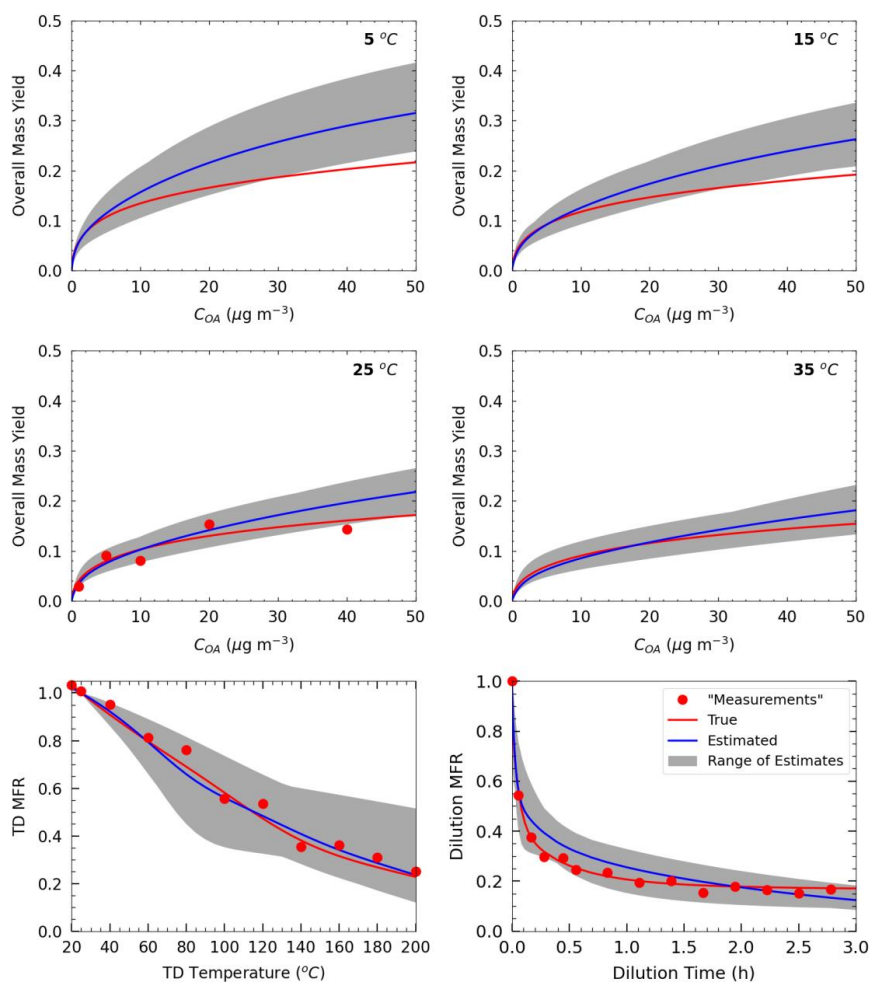

Figure 2: “Measurements” of Test B1 in Experiment B (red dots), true (red line) and estimated (blue line) yields at four temperatures (at 5 °C, 15 °C, 25 °C, and 35 °C), TD (thermogram), and dilution (areogram) values. The grey area shows the range of good solutions.

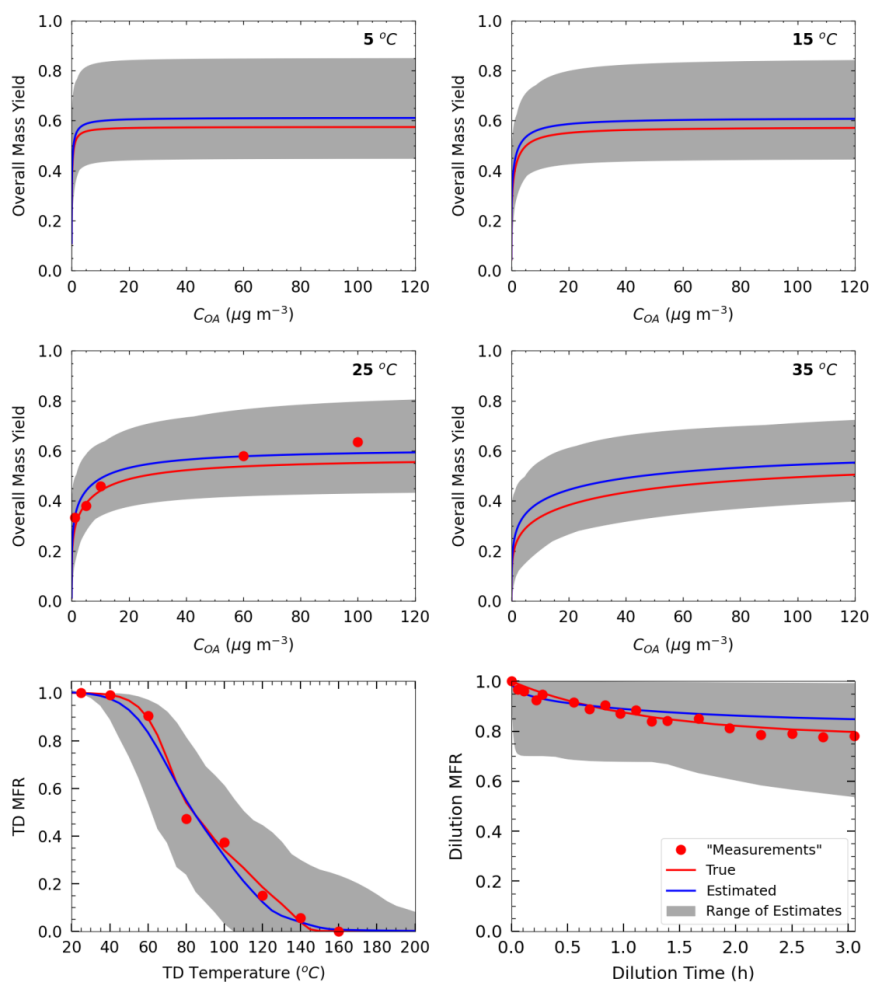

Figure 3: “Measurements” of Test C1 in Experiment C (red dots), true (red line) and estimated (blue line) yields at four temperatures (at 5 °C, 15 °C, 25 °C, and 35 °C), TD (thermogram), and dilution (areogram) values. The grey area shows the range of good solutions.

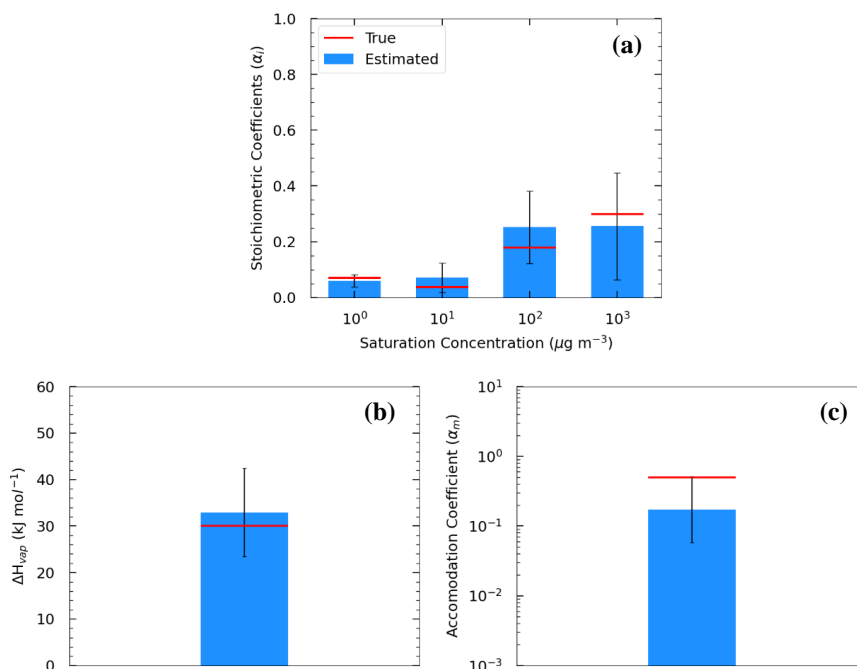

Figure 4. Estimated (bars) and true (red lines) parameter values of Experiment A in Test A1 combining yield, TD, and isothermal dilution measurements for: (a) the volatility distribution of the products, (b) ΔH_{vap} , and (c) α_m . The error bars represent the uncertainty of the estimated values.

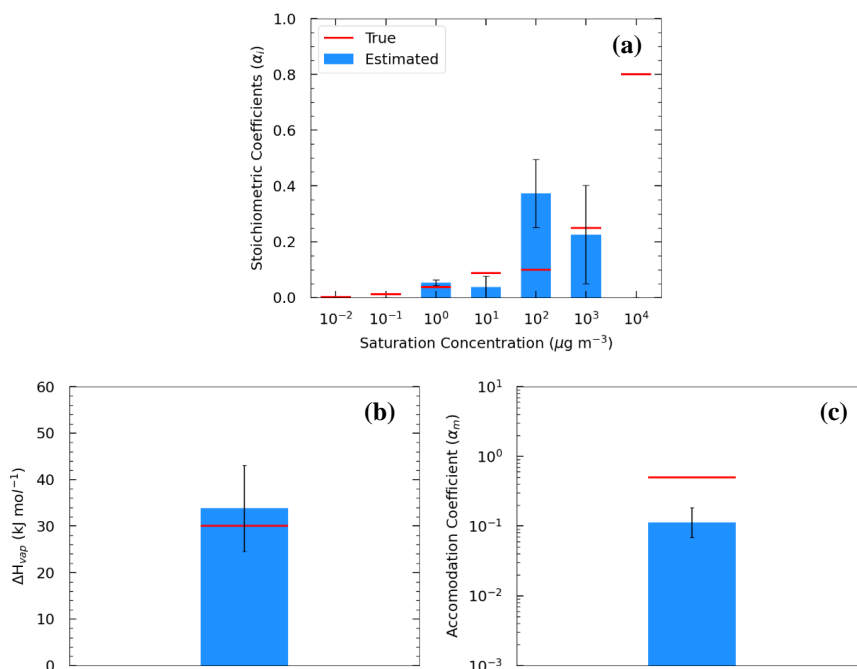

Figure 5: Estimated (bars) and true (red lines) parameter values of Experiment B in Test B1 combining yield, TD, and isothermal dilution measurements for: (a) the volatility distribution of the products, (b) ΔH_{vap} , and (c) α_m . The error bars represent the uncertainty of the estimated values.

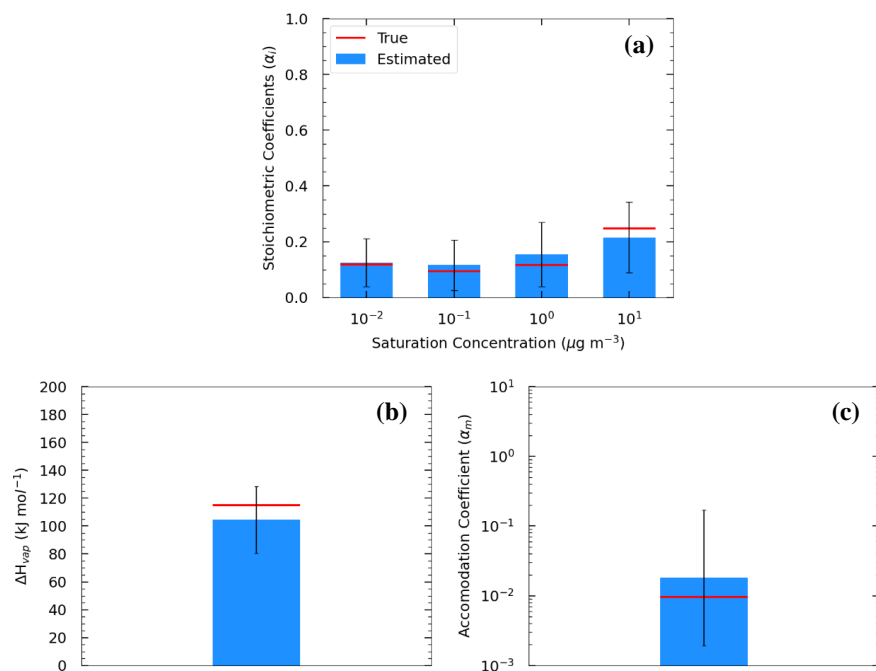

Figure 6: Estimated (bars) and true (red lines) parameter values of Experiment C in Test C1 combining yield, TD, and isothermal dilution measurements for: (a) the volatility distribution of the products, (b) ΔH_{vap} , and (c) α_m . The error bars represent the uncertainty of the estimated values.

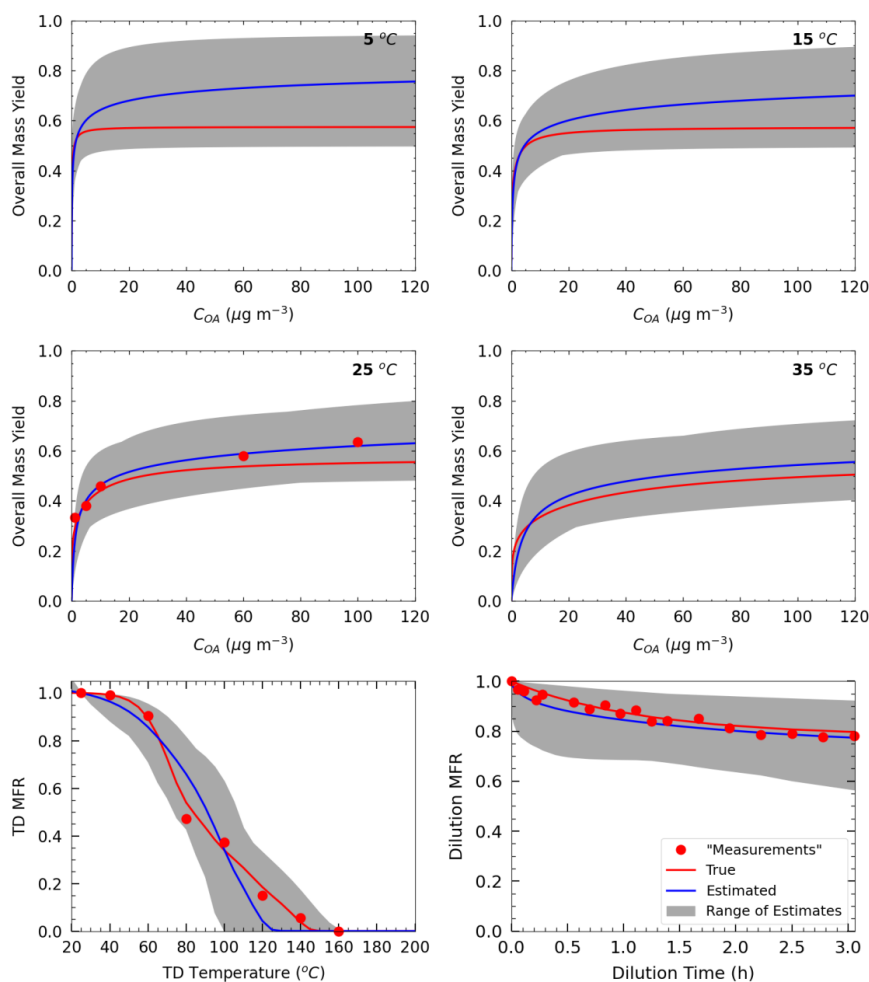

Figure 7: Yields calculated using the “true” parameters of Experiment C (red line) and the estimated (blue line) using the parameters of Test C2 for the following temperatures: 5 °C, 15 °C, 25 °C, and 35 °C. Also shown the thermogram and aerogram. The grey area shows the range of good solutions obtained by our algorithm.

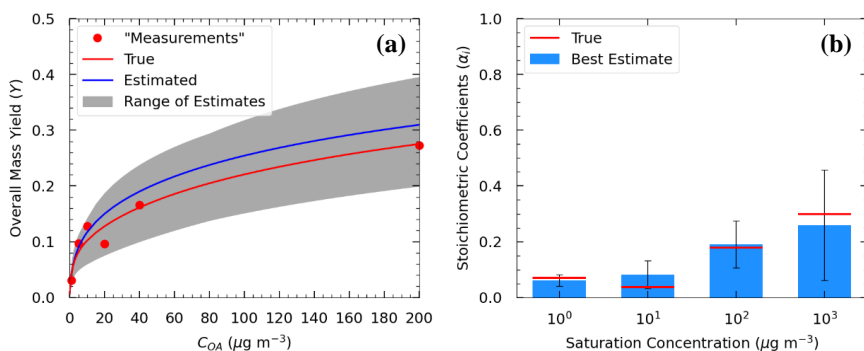

Figure 8: (a) True (red line) and estimated (blue line) yields in Test A4, and the “measurements” of Experiment A (red dots) including an additional yield “measurement” at $200 \mu\text{g m}^{-3}$. (b) Estimated volatility distribution of the products (bars) of Test A4 and the true (red lines) parameter values.

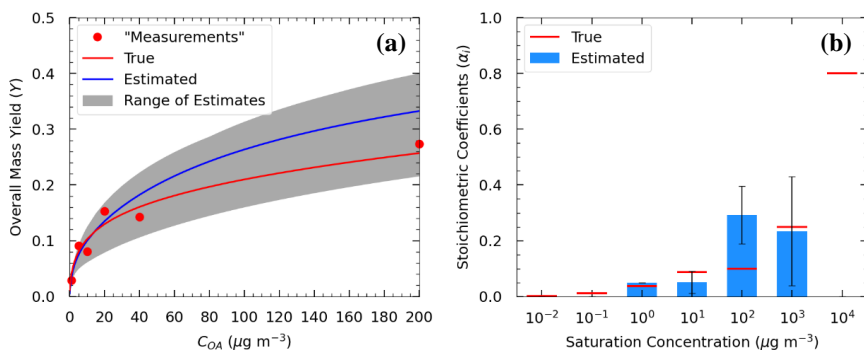

Figure 9: (a) Estimated yields (blue line) in Test B2 and “measurements” of Experiment B (red dots) including an additional yield “measurement” at $200 \mu\text{g m}^{-3}$. (b) Estimated volatility distribution of the products (bars) of Test B2 and the true (red lines) parameter values.

Figure 10: Yields calculated using the “true” parameters of Experiment B (red line) and the estimated (blue line) using the parameters of Test B2 for the following temperatures: 5 °C, 15 °C, 25 °C, and 35 °C. The grey area shows the range of good solutions obtained by our algorithm.
