## Abstract

Retrieval of terrestrial aerosol optical depth (AOD) has been a challenge for satellite Earth observations, mainly due to the difficulty of estimating surface reflectance caused by land-atmosphere coupling. Current satellite AOD retrieval products have low spatial resolution under complex surface processes. In this study, based on our previous studies of AOD retrieval, we further improved the estimation method of surface reflectance by establishing an error correction model, which helped us obtain more accurate AOD retrievals. We constructed a lookup table using the Second Simulation of Satellite Signal in the Solar Spectrum (6S) to achieve high-precision retrieval of AOD. The accuracy of the algorithm's retrieval was verified by AERONET (Aerosol Robotic Network) observations. The results indicated that the retrieved AOD

22 based on the improved method of this study has advantages in terms of fewer missing AOD pixels  
23 and finer spatial resolution, compared to the MODIS AOD product and our previous estimation  
24 method. Among the nine MISR angles, the optimal correlation coefficient (R) of retrieved AOD  
25 and observed AOD can reach 0.89. Root mean square error (RMSE) and relative mean bias (RMB)  
26 can reach minimum values of 0.20 and 0.32, respectively. This study will help to further improve  
27 the accuracy of retrieving multi-angle AOD at large spatial scales and long time series.

29 Keywords: surface reflectance; aerosol optical depth; satellite remote sensing; MISR; MODIS

## 30 **1. Introduction**

31 Aerosols are liquid or solid particles suspended in the atmosphere, with particle diameters  
32 ranging from approximately 0.001 to 100  $\mu\text{m}$  (Giles et al., 2019). Aerosols have a significant  
33 impact on the Earth's radiation budget balance, and estimating their uncertainties is challenging  
34 (Holben et al., 2001; Li et al., 2020; Berhane et al., 2021; Sun et al., 2022). As a result, the direct  
35 and indirect effects of aerosols have garnered widespread attention in the study of climate change  
36 mechanisms (Hatzianastassiou et al., 2009; Dao et al., 2014; Daniel et al., 2014; Samset et al.,  
37 2018; Li et al., 2018; Huang et al., 2021). Additionally, high concentrations of aerosols can pose a  
38 serious threat to human health (Lee et al., 2010; Dehghani et al., 2012; Mironova et al., 2015). The  
39 optical properties of aerosols include parameters such as aerosol optical depth (AOD), scattering  
40 phase function, single scattering albedo, and absorbing optical depth. Among there, AOD is an  
41 important parameter defined as the integral of aerosol extinction coefficient in the vertical  
42 direction. It describes the attenuation effect of aerosols on light and serves as an important  
43 indicator of air pollution levels. Over the past two decades, multi-channel spectrometers on

44 geostationary and polar orbit satellites have been utilized for AOD retrieval. The AOD products  
45 obtained through satellite retrieval are widely employed in the study of atmospheric environment  
46 (Kaufman et al, 1997; Xie et al., 2019; Chen et al., 2021). Although the accuracy of AOD retrieval  
47 has continuously improved, there is still ample room for enhancing in the retrieval results over  
48 land.

49 Scholars have conducted studies using multi-angle sensors. Flowerdew et al. (1996) utilized  
50 Along-Track Scanning Radiometer 2 (ATSR-2) dual-angle observation data, based on the  
51 approximate condition of minimum variation of surface reflectance with wavelength, and using  
52 the assumption of independent invariance of ground features and Lambertian bodies. They  
53 simulated this by using a bidirectional reflection radiation transfer model and proposed a  
54 dual-angle algorithm (ATSR-DV) to retrieve AOD over land. Kokhanovsky et al. (2009) used the  
55 ATSR-DV algorithm to retrieve the AOD over Germany on October 13, 2005, and compared the  
56 retrieval results with MEduium-Resolution Imaging Spectrometer (MERIS) and MISR products.  
57 They indicated that the ATSR-2 algorithm is also suitable for Advanced Along-Track Scanning  
58 Radiometer (AATSR). Sundstrom et al. (2012) obtained an aerosol model of eastern China based  
59 on Aerosol Robotic Network (AERONET) observation data and used the ATSR-DV algorithm to  
60 retrieve the proportion of AOD and coarse to fine particles from AATSR data. Abdou et al. (2005)  
61 compared the MISR AOD and the Moderate-resolution Imaging Spectroradiometer (MODIS)  
62 AOD products carried by Terra using data from 62 AERONET observation sites. The results  
63 showed that over land, the MODIS AOD in the 0.470  $\mu\text{m}$  and 0.660  $\mu\text{m}$  channels was 35% and  
64 10% higher than MISR. In coastal and desert areas, the MODIS retrieval error was relatively large,  
65 while over the ocean, in the 0.470  $\mu\text{m}$  and 0.660  $\mu\text{m}$  channels, the MISR was 0.1 and 0.05 higher

66 than the MODIS AOD value, respectively, mainly depends on the accuracy of radiometric  
67 calibration. Martochik et al. (1997) proposed an algorithm for extracting aerosol optical  
68 parameters using MISR multi-angle observations. The results showed that in the presence of dense  
69 vegetation over land, AOD was extracted using its low reflectivity and multi-angle observations. If  
70 dense vegetation did not exist, AOD and aerosol models were determined using the reflectance  
71 function spectral contrast angle dependence relationship. As a new remote sensing tool,  
72 multi-angle remote sensing has the ability to provide aerosol characteristics such as optical depth,  
73 single scattering albedo, and phase function with sufficient precision, which is more suitable for  
74 playing its unique role in aerosol research than traditional single-angle optical remote sensing  
75 (Dubovik et al., 2019). Multi-angle remote sensing retrieval of aerosol optical properties can  
76 utilize the angle information contained in satellite signals to better separate the contributions of the  
77 surface and atmosphere, making it suitable for some bright surfaces. This provides a new approach  
78 for AOD retrieval.

79       Surface reflectance measures the ability of land to absorb and reflect solar radiation. On land,  
80 surface reflectance is relatively complex and is detected by satellite sensors after atmospheric  
81 scattering and absorption. Satellite observations capture a combination of these two components,  
82 making it challenging to directly separate surface reflectance from atmospheric scattering.  
83 Consequently, the simultaneous retrieval of atmospheric aerosols and surface reflectance is a  
84 primary goal in quantitative satellite remote sensing (Deuzé et al., 2001). In optical remote sensing,  
85 the blue band has shorter wavelengths and low surface reflectivity, resulting in more reflection and  
86 scattering caused by the atmosphere. Therefore, the blue band is commonly used for AOD  
87 retrieval. During the AOD retrieval process, overestimating surface reflectivity leads to

88 underestimating AOD, while underestimating surface reflectance leads to overestimating AOD.  
89 Separating atmospherically generated reflectance from surface reflectance in apparent reflectance  
90 (reflectance at the top of the atmosphere) poses a challenge in AOD retrieval. Generally, aerosol  
91 signals are weaker compared to surface signals (Dong et al., 2023). Previous studies have shown  
92 that an intercept error of 0.01 in surface reflectance can result in a retrieval error of approximately  
93 0.1 when using satellite remote sensing to retrieve AOD (Zhang et al., 2021). Therefore, accurate  
94 estimates of surface reflectance are crucial for reliable aerosol retrieval.

95 A high-precision AOD product obtained from retrieval is of great significance for monitoring  
96 changes in atmospheric pollution and providing decision-making support for pollution control.  
97 Observing the spatial distribution of AOD is crucial for daily air pollution monitoring.  
98 Additionally, aerosol particles can impact the energy balance between the land and the atmosphere  
99 by absorbing and scattering solar radiation, thereby influencing the global climate system. To  
100 enhance the accuracy and resolution of AOD retrieval, this study utilizes data from nine camera  
101 angles in the blue band of MISR L1B2T from 2016 to 2018, employing an improved retrieval  
102 algorithm. Firstly, the study analyzes the retrieval errors of MISR AOD for nine camera angles  
103 prior to the implementation of the improved retrieval approach. Secondly, an error correction  
104 model is established to rectify the estimated surface reflectance of MISR, thus improving the  
105 surface reflectance at these nine angles. The improved surface reflectance retrieval is then used to  
106 obtain highly accurate MISR AOD. Finally, the improved AOD retrieval method is validated, and  
107 its estimated results are compared with the previous retrieval.

## 108 **2. MISR, MODIS, and AERONET Data**

### 109 **2.1 MISR data**

110 In this study, we utilized the MISR Level 1B2 Terrain Data (MI1B2T) and extracted the  
111 radiance data using the HEGTool (HDF-EOS To GeoTIFF Conversion Tool) software. We  
112 selected the corresponding blocks, output data types, and projection based on the regional location  
113 of the 180 radiation blocks and extracted the 64th and 65th blocks covering the Yangtze River  
114 Delta region (Figure S1). Moreover, we extracted the solar zenith angle, solar azimuth angle,  
115 satellite zenith angle, and satellite azimuth angle data for 9 cameras from the angle dataset  
116 (MI1B2GEOP) and selected the corresponding blocks, output data types, and projection  
117 information. To reduce the influence of clouds, we performed cloud detection and cloud pixel  
118 removal on satellite remote sensing images with cloud pixel coverage less than 50% and used a  
119 threshold value in the blue band to remove cloud pixels. However, through repeated experiments,  
120 we found that a fixed threshold could not effectively remove the cloud pixels from the 9 angles of  
121 the MISR sensor (Figures S2 and S3). Therefore, we adopted a dynamic threshold method to  
122 remove the cloud pixels from the MISR data. Details regarding the data used in this study can be  
123 found in Table S2.

### 124 **2.2 MODIS data**

125 In this study, we utilized MODIS L1B data, including radiance data (MOD02/MYD02) and  
126 geolocation data (MOD03/MYD03). The data preprocessing, including radiometric calibration,  
127 butterfly processing, geometric correction, reprojection, and band extraction, was conducted using  
128 the MODIS Conversion Toolkit (MCTK). The MODIS BRDF/Albedo is a standard Level-3

129 product representing surface properties derived from MODIS instruments onboard the Terra and  
130 Aqua satellite platforms. This product has a 16-day retrieval period, and the observations from the  
131 9th day of each 16-day cycle are weighted to generate daily data, known as the global daily  
132 surface albedo product (Hsu et al., 2004). The core dataset for MODIS BRDF product is  
133 MCD43A1.

### 134 **2.3 AERONET data**

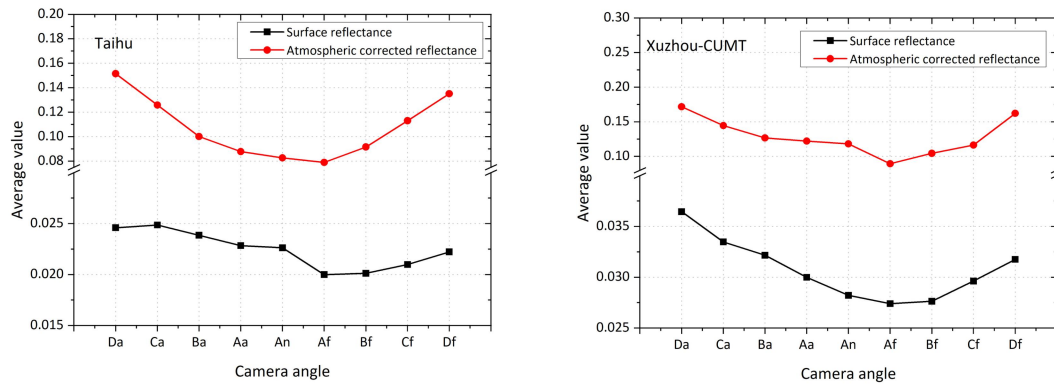

135 This study utilized AERONET measurement stations, which employ CE-318 solar  
136 radiometers produced in France. The instrument measures direct spectral solar radiation every 3  
137 minutes across nine channels: 340nm, 380nm, 440nm, 500nm, 670nm, 870nm, 936nm, 1020nm,  
138 and 1640nm. The measurement at the 936nm channel is used to retrieve the total atmospheric  
139 water vapor content, while the remaining channels are used to derive aerosol optical depth (AOD)  
140 with a retrieval error of approximately 0.01-0.02. Therefore, AERONET provides high-precision  
141 aerosol characteristic parameters and can be used to validate satellite-retrieved AOD (Lu et al.,  
142 2019). In this study, AOD measurements obtained from AERONET were used as ground truth to  
143 verify the accuracy of satellite remote sensing retrievals. AERONET AOD data are categorized  
144 into three quality levels: Level 1.0 (unscreened), Level 1.5 (cloud screened and quality controlled),  
145 and Level 2.0 (quality assured). The study area primarily covers the Yangtze River Delta region,  
146 where AERONET has several stations. However, continuous data were only available from the  
147 Taihu and Xuzhou-CUMT stations, while data from other stations were relatively limited in  
148 duration. Therefore, AERONET Level 1.5 AOD data with a large number of continuous and  
149 current observations were selected for validating MISR AOD retrievals.

### 150 3. Methodology

#### 151 3.1 Problems in the previous surface reflectance estimation method

152 The accurate estimation of surface reflectance is a crucial and challenging aspect in the  
153 retrieval of AOD from satellite remote sensing data (Remer et al., 2009; Gupta et al., 2016).  
154 Previous research has identified the variation patterns of 9-angle MISR AOD (Chen et al., 2021).  
155 However, the AOD retrieved at 9 angles exhibits relatively large errors when compared to  
156 AERONET AOD (Table S3). Atmospheric correction can eliminate the effects of clouds and  
157 aerosols on data, obtaining the true surface reflectance. When using the 6S model to calculate  
158 atmospheric correction reflectance for the MISR sensor, several parameters need to be inputted,  
159 including geometric parameters, AOD, aerosol types, sensor radiance data, and sensor altitude, etc.  
160 In this study, we inputted the MISR geometric parameters and radiation data corresponding to  
161 Taihu and Xuzhou-CUMT stations, while the AOD parameter inputted was the AERONET AOD  
162 for these two stations. Through the generated linear atmospheric correction formula, we calculated  
163 the atmospheric correction reflectance for each pixel. To investigate the reasons for the higher  
164 AOD values retrieved from the 9 MISR angles, this study compared the MISR atmospheric  
165 correction reflectance and MISR surface reflectance at the pixel location (Figure 1) (MISR surface  
166 reflectance calculation method referenced Chen et al. (2021)). It was observed that the MISR  
167 surface reflectance was relatively lower compared to the MISR atmospheric correction reflectance.  
168 As a result, the retrieved MISR AOD values were higher compared to AERONET AOD. Therefore,  
169 it is necessary to establish a correction model to adjust the MISR surface reflectance and improve  
170 the retrieval accuracy of MISR AOD.

171 Figure 1. Comparison of MISR surface reflectance with atmospheric corrected reflectance in the  
 172 blue band (At the pixel locations of Taihu and Xuzhou-CUMT sites).

### 173 3.2 Improved surface reflectance estimation method

174 To develop a correction model that improves the surface reflectance, the design scheme of  
 175 this study is shown below:

#### 176 (1) Calculation of MODIS atmospheric corrected reflectance

177 The atmospheric correction of MODIS L1B was carried out using the 6S model to obtain  
 178 MODIS atmospheric corrected reflectance. When using the 6S model to calculate the atmospheric  
 179 correction reflectance of the MODIS sensor, several parameters need to be provided, including  
 180 geometric parameters, AOD, atmospheric models, aerosol types, sensor radiance data, sensor  
 181 altitude, and spectral parameters. In this study, we used the MODIS geometric parameters and  
 182 radiance data corresponding to the Taihu and Xuzhou-CUMT sites. The AOD parameter was  
 183 obtained from the AERONET AOD data measured at these two sites. The atmospheric models  
 184 chosen were mid-latitude winter and mid-latitude summer to account for seasonal variations in  
 185 atmospheric transmission. The aerosol type selected was continental aerosol since it is typically  
 186 found in the Yangtze River Delta region. The sensor altitude was set to the height of satellite  
 187 observations. The spectral parameters were defined based on the wavelength bands of the MODIS

188 sensor. By providing these parameters, we can utilize the 6S model to calculate the atmospheric  
 189 correction reflectance of the MODIS sensor.

190 (2) Calculation of surface bidirectional reflectance

191 We utilized the MODIS BRDF/Albedo product MCD43A1 data and employed the Ross-Li  
 192 model to simulate surface bidirectional reflectance under MODIS and MISR observation  
 193 geometries. The linear kernel-driven BRDF model comprises three essential parameters: the  
 194 nadir-view reflectance, and the weighting coefficients for the two kernel functions. The model can  
 195 be computed using formulas 1-9.

$$196 \quad BRDF(\theta_s, \theta_v, \phi) = f_{iso}(\Lambda) + f_{vol}(\Lambda)K_{vol}(\theta_s, \theta_v, \phi) + f_{geo}(\Lambda)K_{geo}(\theta_s, \theta_v, \phi) \quad (1)$$

$$197 \quad K_{vol}(\theta_s, \theta_v, \phi) = \frac{(\pi/2 - \xi)\cos\xi + \sin\xi}{\cos\theta_s + \cos\theta_v} - \frac{\pi}{4} \quad (2)$$

$$198 \quad K_{geo}(\theta_s, \theta_v, \phi) = O(\theta_s, \theta_v, \phi) - \sec\theta'_s - \sec\theta'_v + \frac{1}{2}(1 + \cos\xi')\sec\theta'_s \sec\theta'_v \quad (3)$$

$$199 \quad O(\theta_s, \theta_v, \phi) = \frac{1}{\pi}(t - \sin t \cos t)(\sec\theta'_s + \sec\theta'_v) \quad (4)$$

$$200 \quad \cos t = \frac{h \sqrt{D^2 + (\tan\theta'_s \tan\theta'_v \sin\phi)^2}}{b \sec\theta'_s + \sec\theta'_v} \quad (5)$$

$$201 \quad D = \sqrt{\tan^2\theta'_s + \tan^2\theta'_v - 2\tan\theta'_s \tan\theta'_v \cos\phi} \quad (6)$$

$$202 \quad \cos\xi' = \cos\theta'_s \cos\theta'_v + \sin\theta'_s \sin\theta'_v \cos\phi \quad (7)$$

$$203 \quad \theta'_s = \tan^{-1}\left(\frac{b}{r} \tan\theta_s\right) \quad (8)$$

$$204 \quad \theta'_v = \tan^{-1}\left(\frac{b}{r} \tan\theta_v\right) \quad (9)$$

205 In the aforementioned equation,  $BRDF(\theta_s, \theta_v, \phi)$  represents the bidirectional reflectance of  
 206 the surface, while  $\theta_s$ ,  $\theta_v$ , and  $\phi$  denote the solar zenith angle, view zenith angle, and relative  
 207 azimuth angle, respectively.  $\Lambda$  stands for the bandwidth, while  $K_{vol}(\theta_s, \theta_v, \phi)$  and  
 208  $K_{geo}(\theta_s, \theta_v, \phi)$  represent the volumetric scattering kernel and geometric optical scattering kernel,

209 respectively. These terms are all functions of the incident and viewing angles.  $f_{iso}$ ,  $f_{vol}$ , and  
 210  $f_{geo}$  correspond to the weights assigned to isotropic scattering, volumetric scattering, and  
 211 geometric optical scattering in the reflectance, which serve as coefficients for their respective  
 212 kernel functions.  $\xi$  represents the scattering angle, while b, h, and r represent the vertical radius,  
 213 horizontal radius, and height of the sphere's center, respectively. Based on empirical values, these  
 214 three parameters can be considered as fixed values. Within the production process of MODIS  
 215 BRDF model parameter products, the following relationships exist among these parameters:  $h/b=2$   
 216 and  $b/r=1$  (Schaaf et al., 1999). By utilizing extrapolation with kernel functions, the surface's  
 217 bidirectional reflectance can be computed under arbitrary solar incident and satellite viewing  
 218 directions using the aforementioned equation.

### 219 (3) Improved calculation of surface reflectance by MISR

220 The new estimated MISR surface reflectance based on the MODIS atmospheric correction  
 221 was calculated by bringing the MODIS atmospheric correction reflectance into Eq. 10 and Eq. 11.  
 222 The MISR surface reflectance was combined with the newly estimated MISR surface reflectance,  
 223 and a regression was fitted (with 60% of the overall sample data randomly selected) to create a  
 224 surface reflectance error correction model, as shown in the following formula:

$$225 \quad \rho(\theta_s, \theta_v, \phi)_{MISR\_a} = \rho(\theta_s, \theta_v, \phi)_{MODIS\_at} \times \frac{BRDF(\theta_s, \theta_v, \phi)_{MISR}}{BRDF(\theta_s, \theta_v, \phi)_{MODIS}} \quad (10)$$

226 In Eq. 10,  $BRDF(\theta_s, \theta_v, \phi)_{MISR}$ ,  $BRDF(\theta_s, \theta_v, \phi)_{MODIS}$  are BRDFs obtained at MISR and  
 227 MODIS angles, respectively.  $\theta_s$  is the solar zenith angle,  $\theta_v$  is the satellite zenith angle, and  $\phi$   
 228 is the relative azimuth angle.  $\rho(\theta_s, \theta_v, \phi)_{MISR\_a}$  is the surface reflectance of MODIS at the  
 229 geometric observation angle of MISR, and  $\rho(\theta_s, \theta_v, \phi)_{MODIS\_at}$  is the MODIS atmospheric  
 230 corrected reflectance.

231 This study selected spectral data containing 28 typical features of different types of  
 232 vegetation, soil and water bodies from five standard spectral libraries that come with the ENVI  
 233 software. The surface reflectance of different features in the blue bands of MODIS and MISR was  
 234 calculated using formulas (Chen et al., 2021).

$$235 \quad \rho(\theta_s, \theta_v, \phi)_{MISR} = \rho(\theta_s, \theta_v, \phi)_{MISR\_a} \times 0.9834 - 0.0081 \quad (11)$$

236 The New MODIS surface reflectance ( $\rho(\theta_s, \theta_v, \phi)_{MISR\_a}$ ) at the MISR angle obtained from  
 237 Eq. 11 is converted to the MISR surface reflectance by Eq. 11.

238 The MISR surface reflectance estimated by Eq. 11 is transformed using an error correction  
 239 model to obtain the final improved MISR surface reflectance. The improved MISR surface  
 240 reflectance will be used in the retrieval of the AOD. The MISR correction model was developed  
 241 by fitting a linear regression of the previously estimated MISR surface reflectance based on the  
 242 MODIS V5.2 algorithm to the MISR surface reflectance estimated based on the MODIS  
 243 atmospheric correction (60% of the data were randomly selected) as shown in Eq.12. The  
 244 previously estimated 9-angle MISR surface reflectance was error-corrected by Eq. 12 to obtain the  
 245 improved surface reflectance for the 9 angles of the MISR sensor, which was ultimately used to  
 246 perform the MISR AOD retrieval for the 9 angles.

$$247 \quad \rho(\theta_s, \theta_v, \phi)_{MISR-b}^* = \rho(\theta_s, \theta_v, \phi)_{MISR} \times 0.9209 + 0.0409 \quad (12)$$

248 Where  $\rho_{MISR-b}^*$  is the improved MISR surface reflectance in Eq. 12.

### 249 **3.3 Flow of improved multi-angle AOD retrieval**

250 The flow of the improved surface reflectance algorithm for this study is shown in Figure 2.  
 251 The MODISL1B data were first atmospherically corrected using 6S. Then, the MISR surface

252 reflectance estimated from previous study was combined with the new MISR surface reflectance  
253 estimated from Eq. 11 to build a MISR error correction model for obtaining the improved MISR  
254 surface reflectance (Chen et al., 2021). The study retrieved the MISR AOD for nine camera angles  
255 using improved MISR surface reflectance. We validated the improved MISR AOD with  
256 AERONET AOD. We compared the improved AOD with the previously retrieved AOD and  
257 analyzed the accuracy and spatial distribution trends of the improved AOD. The AOD retrieval  
258 method used in this study is based on chen et al. (2021). In our study, we used continental aerosols  
259 for AOD retrieval and atmospheric correction using the 6S model. The selection of an appropriate  
260 aerosol type is crucial for obtaining accurate aerosol optical depth. Previous studies have shown  
261 that continental aerosols can be used to estimate aerosol optical depth in the Yangtze River Delta  
262 region (He et al., 2015). We employed the same aerosol type for AOD retrieval and atmospheric  
263 correction and utilized the 6S model for atmospheric correction. Thus, this study did not consider  
264 the potential error propagation caused by aerosol type and atmospheric correction.

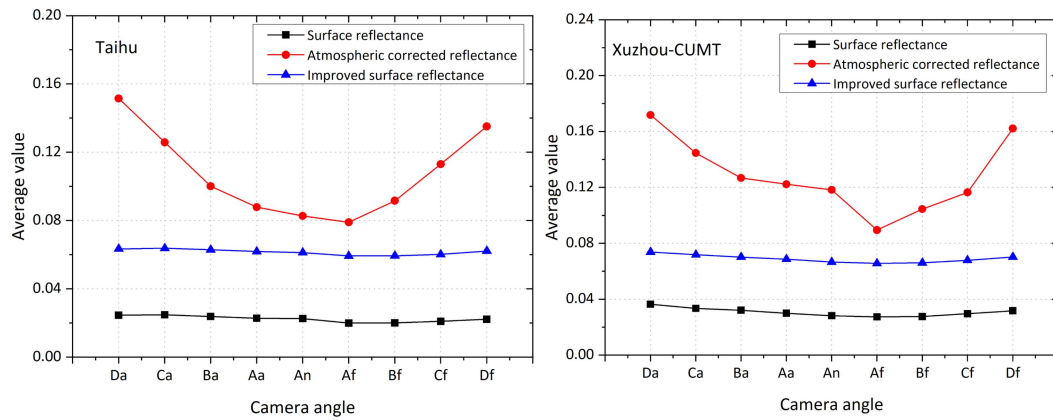

265  
266 Figure 2. Flow chart of the improved MISR surface reflectance algorithm

267 **4. Results and discussion**

268 **4.1 Improved MISR surface reflectance variation characteristics**

269 The estimated MISR surface reflectance, the MISR atmospherically corrected reflectance,  
 270 and the improved MISR surface reflectance are presented in Figure 3. These values represent the  
 271 average of all sample data collected at the corresponding locations at the two sites, Taihu and  
 272 Xuzhou-CUMT, during the valid dates of 2016-2018. It is worth noting that at both the Taihu and  
 273 Xuzhou-CUMT sites, the nine-camera-angle MISR-improved surface reflectance values are  
 274 generally higher than the MISR surface reflectance and lower than the MISR atmospherically  
 275 corrected reflectance. The nine-camera-angle MISR surface reflectance values ranged from 0.02 to

276 0.04. On average, the improved surface reflectance values higher than the previously estimated  
 277 MISR surface reflectance.

278 **Figure 3.** The comparison of MISR surface reflectance, atmospheric corrected reflectance and  
 279 improved surface reflectance in the blue band (This is the multi-year average of the sample data  
 280 for the two sites in Taihu and Xuzhou-CUMT).

281

282 To clarify the trend of the improved surface reflectance, the study conducted a time-series  
 283 analysis of the MISR surface reflectance and the improved surface reflectance (Figure 4). It is  
 284 evident from the analysis that the improved MISR surface reflectances are consistently higher than  
 285 the previously estimated MISR surface reflectances. The MISR surface reflectance values  
 286 generally range from 0-0.05, while the improved surface reflectance values range approximately  
 287 from 0.05-0.1. Overall, there has been an increase in the improved surface reflectance values.

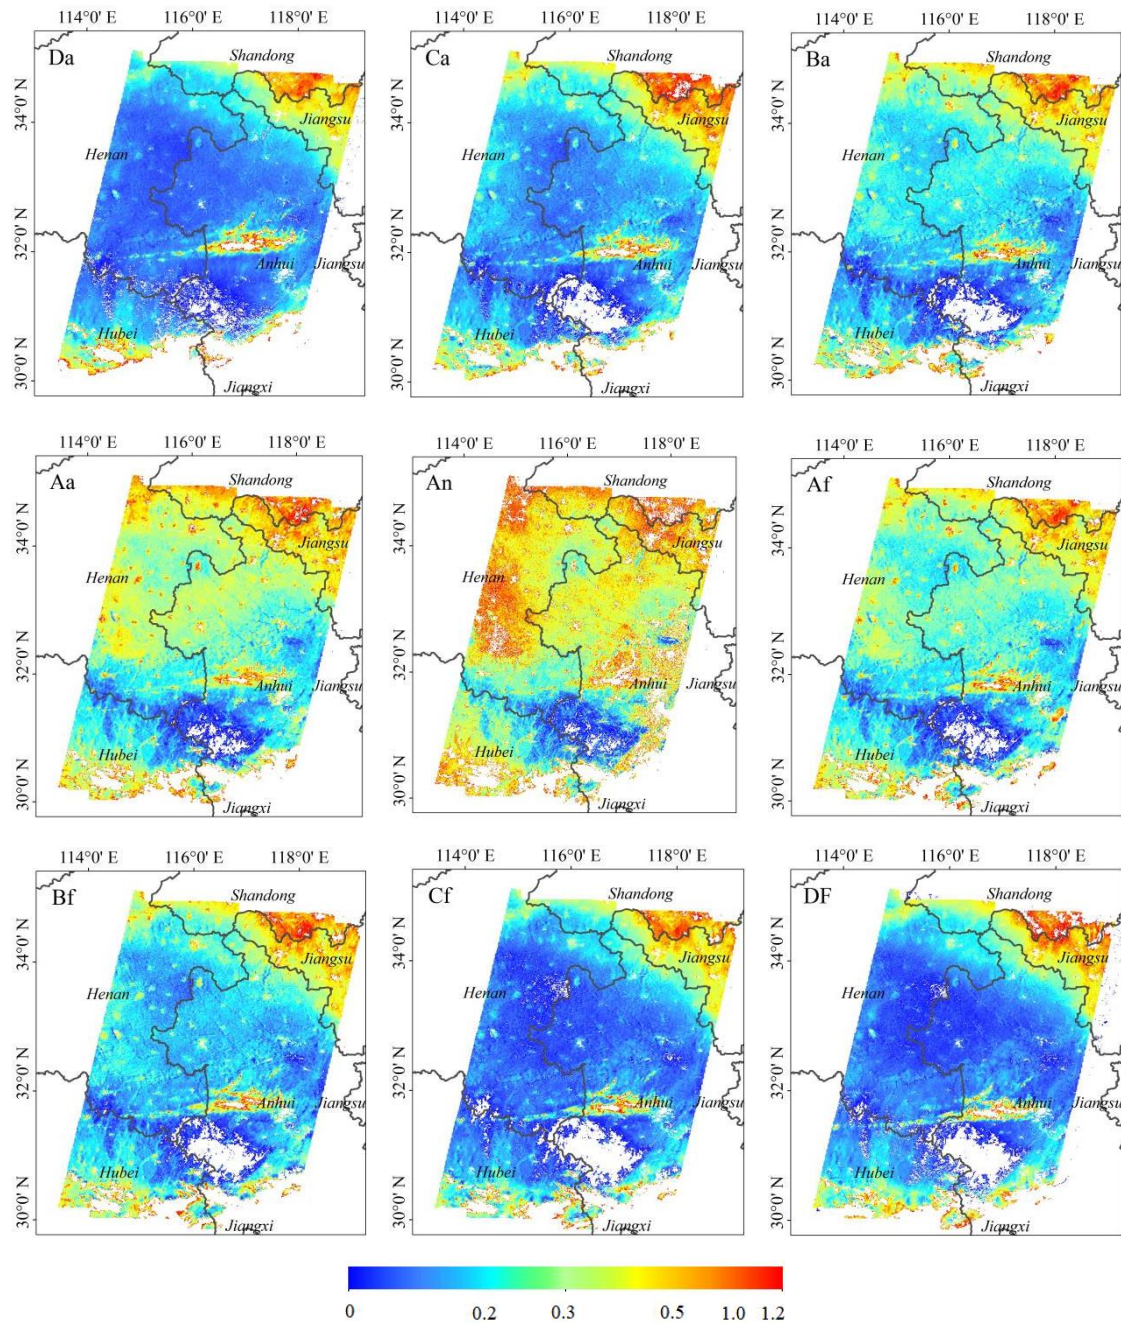

288 **Figure 4.** Surface reflectance time series of MISR sensors in the blue band at 9 observation angles.

289 (The order of time from front to back for 9 angles is shown in Table S2)

#### 290 **4.2 Results of the Improved MISR AOD retrieval**

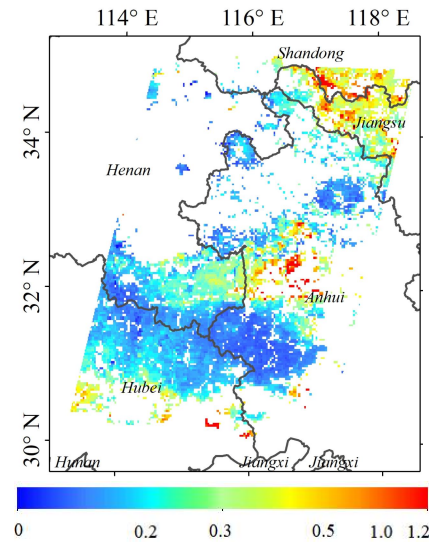

291 MISR AOD values for 2016-2018 were obtained using an improved surface reflectance  
 292 retrieval. The study presents the retrieval results from nine camera observation angles of the MISR  
 293 sensor on 12 June 2018 (Figure 5). From the spatial distribution of AOD, it is evident that the  
 294 retrieval results in the study area do not exceed a value of 1. The overall spatial distribution trend  
 295 is generally consistent with the results before the improvement (Chen et al., 2021), but there are  
 296 differences in the magnitude of the values. Values in the north-eastern and southern regions range  
 297 from 0.5 to 1, indicating poor air quality to some extent in these areas. The AOD values retrieved  
 298 from the five camera observation angles, Ba, Aa, An, Af, and Bf, fall within the approximate  
 299 range of 0.25-0.5. In the central region, the AOD values from the four camera observation angles,  
 300 Da, Ca, Cf, and Df, are mostly in the range of 0-0.25. The values suggest that the air quality in the  
 301 central region is generally good, with some areas experiencing light air pollution. The higher AOD  
 302 in the southern part of Shandong Province and the northern part of Jiangsu Province may be  
 303 attributed to increased local aerosol emissions resulting from human activities.

304 **Figure 5.** Plot of AOD 550nm retrieval results for the improved MISR 9 camera angles on 12  
 305 June 2018.

306 The study validates our improved MISR AOD spatial distribution results by comparing them  
 307 with MODIS AOD products on the same date (Figure 6). The MODIS AOD products have a  
 308 resolution of 3km. It can be observed that the trend of the spatial distribution of MODIS AOD  
 309 products is consistent with the improved MISR AOD. However, the MODIS AOD product has

310 more missing data, which can be avoided by using AOD obtained from the retrieval of the  
311 improved algorithm. Additionally, the AOD retrieval through the improved algorithm has a higher  
312 resolution when compared to the image quality of the MISR AOD product.

313 **Figure 6.** MODIS AOD 550nm product spatial distribution on June 12, 2018

#### 314 **4.3 Verification of the improved MISR AOD**

315 There are many AERONET sites in the Yangtze River Delta region, but currently, only the  
316 Taihu and Xuzhou-CUMT sites continue to provide data, and other sites have a limited time frame  
317 for obtaining data. Therefore, the Taihu and Xuzhou-CUMT sites, which have more data, were  
318 selected for verification. To verify the retrieved MISR AOD, we selected effective AOD records  
319 in the 550nm band within a 30-minute interval between the AERONET ground observation site  
320 and the Terra satellite. The 9 camera views of MISR require approximately 7 minutes to observe  
321 the same geographical location, with relatively short intervals. Therefore, we used the calculated  
322 AERONET AOD average as the approximate truth value and compare it with the retrieved MISR  
323 AOD to verify and reduce errors caused by time difference. In terms of space, we selected pixels

324 observed by the MISR sensors from 9 angles and compared them with the nearest data observed  
325 by AERONET, which can reduce errors caused by spatial differences. As the solar photometer  
326 does not have a 550nm wavelength that corresponds to the retrieval results, the AOD at 550nm  
327 was calculated by applying Angstrom (Eq. 13).

$$328 \quad \tau(\lambda) = \beta\lambda^{-\alpha} \quad (13)$$

329 In the formula,  $\tau(\lambda)$  is the AOD at wavelength  $\lambda$ ,  $\beta$  is the concentration of the entire  
330 atmospheric aerosol, and  $\alpha$  is the wavelength index of Angstrom.

331 In this study, four parameters will be used to assess the accuracy of the remotely sensed AOD  
332 dataset, namely the correlation coefficient (R), the root mean square error (RMSE), p-value and  
333 the relative mean bias (RMB). The specific calculation principles for the three parameters R,  
334 RMSE and RMB are shown in Eq. 14-16. The validation results of this study's improved AOD  
335 dataset from 2016-2018 at Taihu and Xuzhou-CUMT sites are shown in Figure 7 and Figure 8.

336 In general, the scatter plot is distributed above and below the 1:1 line. R is a parameter used  
337 to characterize the correlation between the remote sensing retrieval results and the ground-based  
338 retrieval results. At the Taihu site, R reach up to 0.89, and at the Xuzhou-CUMT site, R reach up  
339 to 0.85. The RMSE is a parameter used to characterize the absolute error of the remote sensing  
340 retrieval results, with a minimum root mean square error of 0.21 at the Taihu site and 0.20 at the  
341 Xuzhou-CUMT site. RMB is the parameter used to characterize the relative error of the remote  
342 sensing retrieval results, with a minimum RMB of 0.52 at the Taihu site and 0.32 at the  
343 Xuzhou-CUMT site. In summary, by comparing the results with the validation of the AOD scatter  
344 plot before the improvement, the accuracy of the nine camera observation angles at both sites has  
345 improved after the improvement (Table 1). In Table 1, R represents the correlation between the

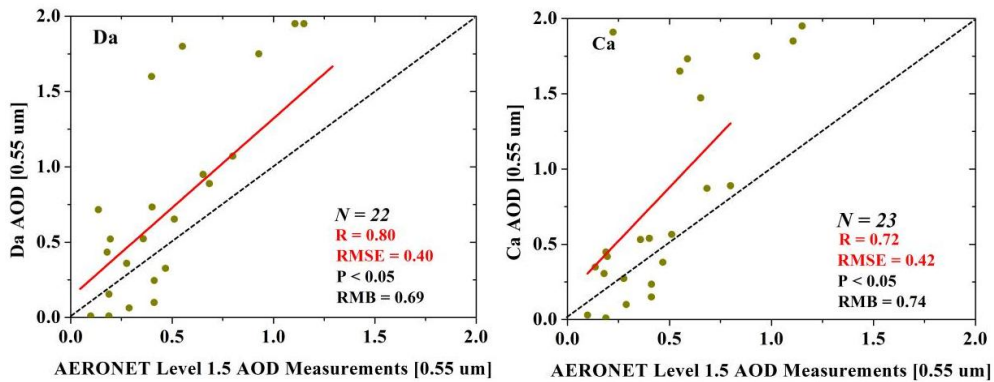

346 old AOD retrieval results and AERONET AOD. RMB represents the relative deviation between  
 347 the old algorithm-retrieved AOD and AERONET AOD. Improved R represents the correlation  
 348 between the improved AOD retrieval results and AERONET AOD. Improved RMB represents the  
 349 relative deviation between the AOD retrieved using the improved algorithm and AERONET  
 350 AOD.

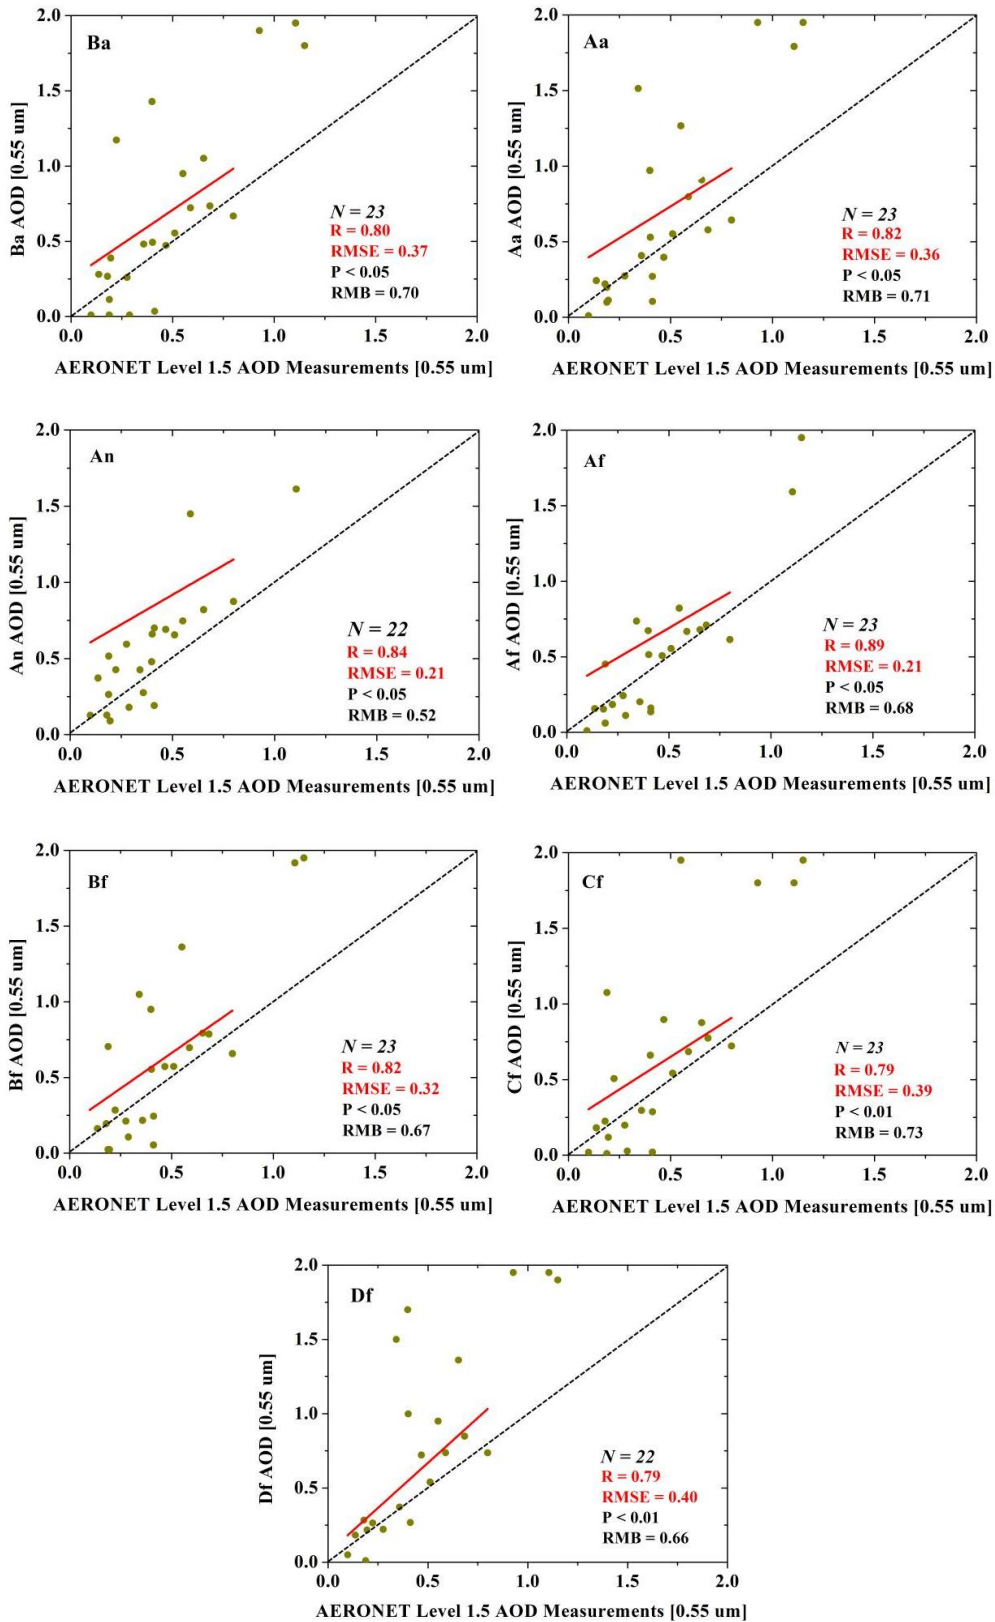

$$351 \quad R = \frac{\sum_{i=1}^N (A_i - \bar{A})(A'_i - \bar{A}')}{\sqrt{\sum_{i=1}^N (A_i - \bar{A})^2 \sum_{i=1}^N (A'_i - \bar{A}')^2}} \quad (14)$$

$$352 \quad RMSE = \sqrt{\sum_{i=1}^N (A_i - A'_i)^2 / N} \quad (15)$$

$$353 \quad RMB = \sum_{i=1}^N (A_i - A'_i) / N \quad (16)$$

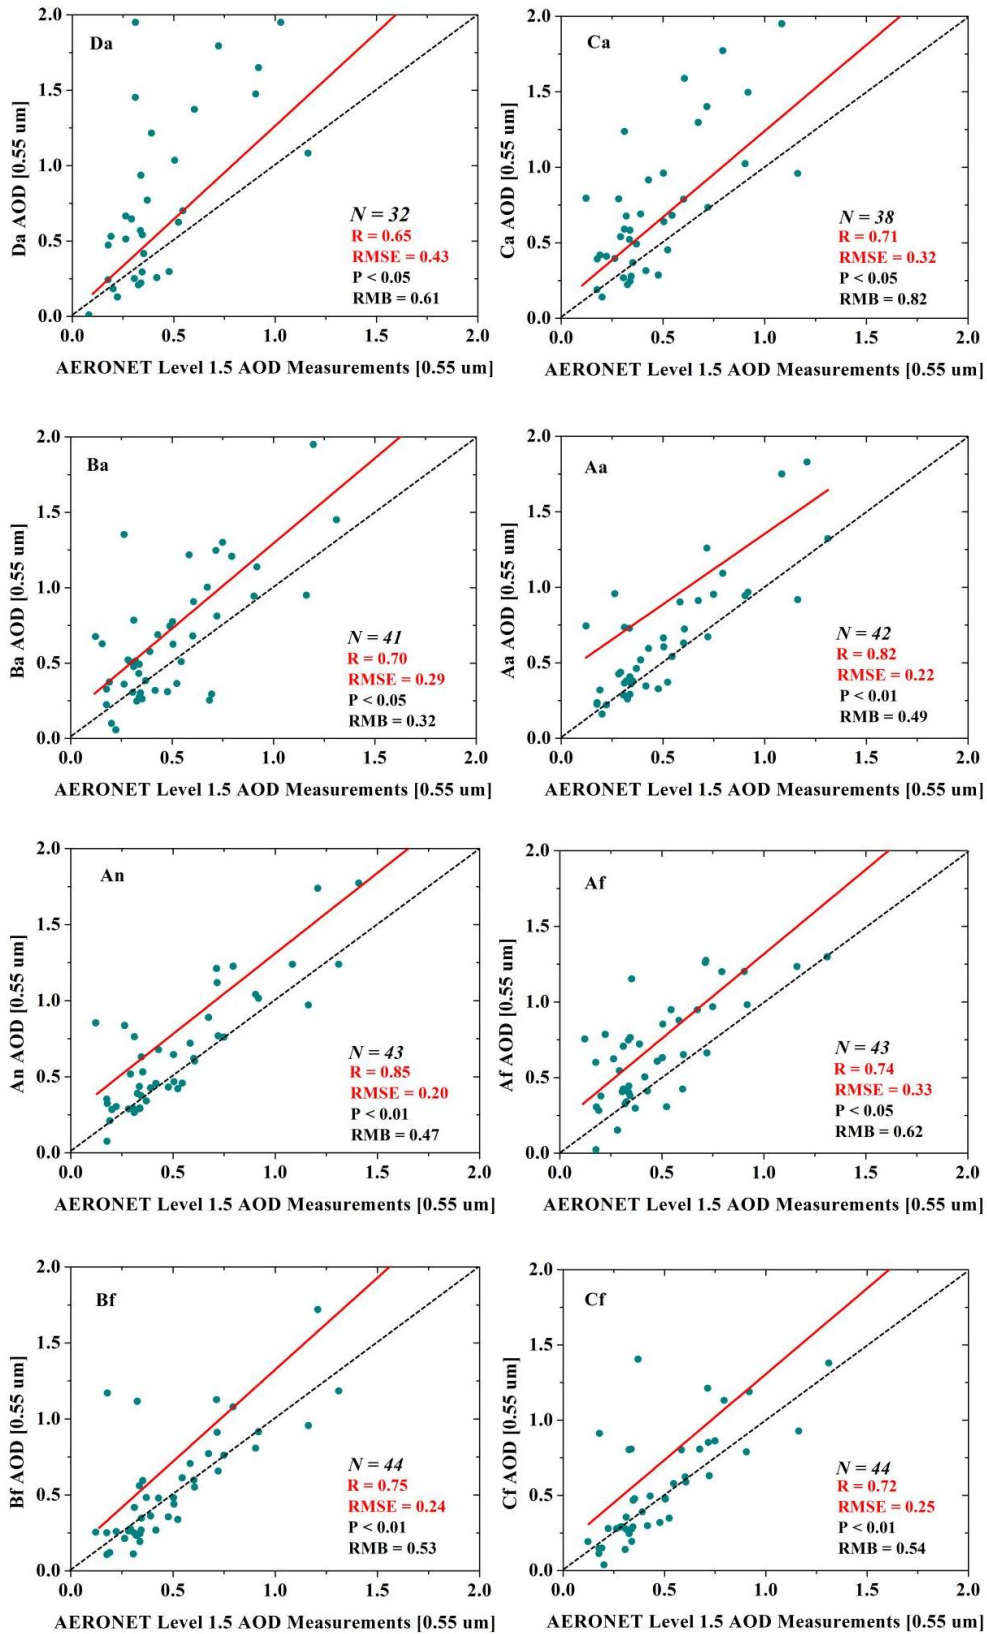

354 where  $A_i$  is the retrieve MISR AOD,  $A'_i$  is the corresponding AERONET AOD,  $\bar{A}$   
 355 and  $\bar{A}'$  are the mean values of the retrieve MISR AOD and AERONET AOD, respectively.  $N$  is  
 356 the number of valid matching results for AERONET AOD and MISR AOD.

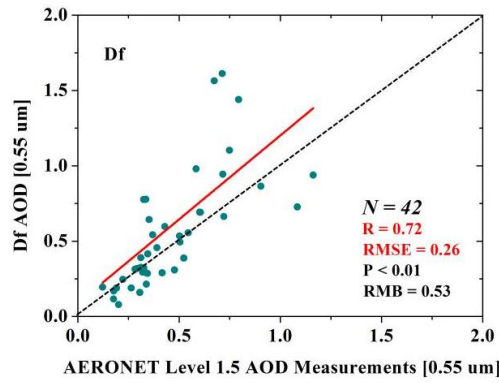

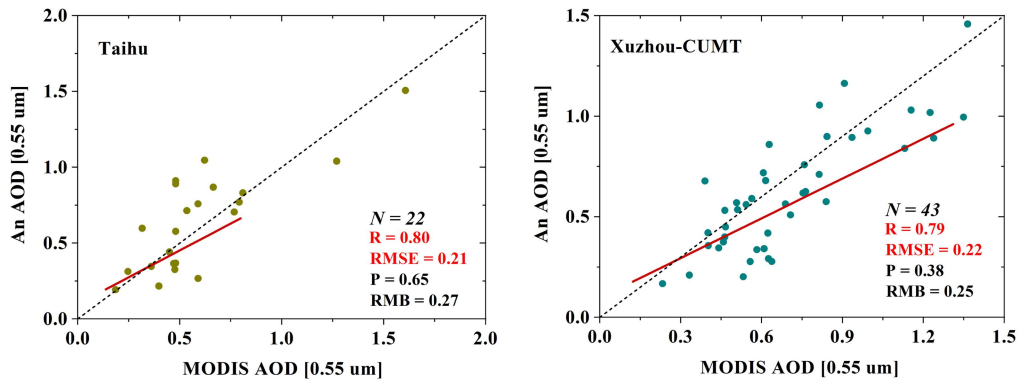

357 **Figure 7.** Comparison between improved MISR AOD and AERONET AOD at Taihu site (N is

358 the number of verification points, red line represents a linear fitting line).

359 **Figure 8.** Comparison between improved MISR AOD and AERONET AOD at Xuzhou-CUMT  
 360 site (N is the number of verification points, red line represents a linear fitting line).

361  
 362 **Figure 9.** Comparison of validation of retrieved AOD with MODIS AOD product

363 **Table 1.** Precision comparison of MISR AOD and AERONET AOD before  
 364 and after improvement

Site	Angle	R	RMB	Improved R	Improved RMB
Taihu	Da	0.77	1.08	0.80	0.69
	Ca	0.70	1.00	0.72	0.74
	Ba	0.77	0.61	0.80	0.70
	Aa	0.81	0.68	0.82	0.71
	An	0.45	1.22	0.84	0.52
	Af	0.72	0.87	0.89	0.68
	Bf	0.72	0.60	0.82	0.67
	Cf	0.57	0.65	0.79	0.73
Df	0.77	0.47	0.79	0.66	
Xuzhou-	Da	0.45	1.58	0.65	0.61

CUMT	Ca	0.59	0.96	0.71	0.82
	Ba	0.67	0.78	0.70	0.32
	Aa	0.73	0.78	0.82	0.49
	An	0.75	0.85	0.85	0.47
	Af	0.72	0.63	0.74	0.62
	Bf	0.62	0.65	0.75	0.53
	Cf	0.68	0.66	0.72	0.54
	Df	0.67	0.65	0.72	0.53

365

366 By comparing the validation results of MODIS AOD products with those of observation sites  
367 (Taihu:  $R=0.59$ ,  $RMSE=0.19$ ,  $P<0.05$ ,  $RMB=0.52$ ; Xuzhou-CUMT:  $R=0.71$ ,  $RMSE=0.25$ ,  $P<0.05$ ,  
368  $RMB=0.44$ ) (Chen et al., 2021), we find that the improved MISR AOD has a higher correlation  
369 with MODIS AOD products in the Taihu and Xuzhou-CUMT sites. The smaller observation angle  
370 of the improved MISR AOD, the closer the error is to that of the MODIS AOD product. The  
371 observation angle of MISR An is the same as that of MODIS. Therefore, we selected An  
372 observation angle and MODIS AOD products at two pixel positions in Taihu and Xuzhou-CUMT  
373 for verification (Figure 9). The results show that the An AOD retrieval by the improved algorithm  
374 correlates well with the MODIS AOD product, and the position errors of the two image elements  
375 are close to each other. The RMSE of the Xuzhou-CUMT site is slightly higher than that of Taihu  
376 site, and the RMB of Taihu site is slightly higher than that of the Xuzhou-CUMT site.

## 377 5. Conclusion

378 This study first explored the problem of estimating the surface reflectance in our previous  
379 study. We obtained an error correction model for surface reflectance by using a linear fit of the  
380 MISR surface reflectance and a new estimate of the MISR surface reflectance. The improved  
381 MISR surface reflectance was obtained through the error correction model. We then retrieved a

382 new AOD product using the improved surface reflectance and a lookup table constructed from the  
383 6S model. Two AERONET ground observation sites with longer time series were used to validate  
384 the AOD obtained by satellites.

385 (1) Overall, the improved AOD and its spatial distribution trends are consistent with our  
386 previous results. The AOD estimated by our improved method exhibited higher accuracy and a  
387 high degree of agreement with the AERONET ground-based observational AOD.

388 (2) More importantly, compared to the MODIS AOD products, the retrieved AOD in this  
389 study has fewer missing AOD pixels and finer spatial resolution. The retrievals of An AOD by the  
390 improved algorithm are highly correlated with the MODIS AOD products, as shown through  
391 validation with the MODIS AOD product.

392 (3) In the future, more aerosol models that conform to the actual situation in the study area  
393 can be constructed using the AERONET ground observation data and introduced into the MISR  
394 AOD retrieval algorithm to further improve the accuracy of the AOD retrieval results. In this study,  
395 the AERONET AOD was used as the true value and as an input for the AOD parameter in the 6S  
396 model for atmospheric correction of MISR and MODIS images. We then obtained a surface  
397 reflectivity error correction model to retrieve the AOD for the entire region. It should be  
398 emphasized that the more AERONET sites used to train the corrected model, the more accurate  
399 the AOD results obtained by this method. However, the data from the AERONET ground  
400 observation sites were limited. In the future, the study area can be expanded on a large scale and  
401 for a longer time series.
