14 **Abstract**

15 The Cloud-Aerosol Lidar with Orthogonal Polarization (CALIOP) onboard the Cloud-Aerosol Lidar and
16 Infrared Pathfinder Satellite Observation (CALIPSO) satellite has been widely used in climate and
17 environment studies to obtain the vertical profiles of atmospheric aerosols. To retrieve the vertical profile of
18 aerosol extinction, the CALIOP algorithm assumes column-averaged lidar ratios based on a clustering of
19 aerosol optical properties measured at surface stations. On one hand, these lidar ratio assumptions may not
20 be appropriate or representative at certain locations. On the other hand, the two-wavelength design of
21 CALIOP has the potential to constrain aerosol size information, which has not been considered in the
22 operational algorithm. In this study, we present a modified inversion algorithm to simultaneously retrieve
23 aerosol extinction and effective radius profiles using two-wavelength elastic lidars such as the CALIOP.

24 Specifically, a look-up table is built to relate the lidar ratio with the Ångström exponent calculated using
25 aerosol extinction at the two wavelengths, and the lidar ratio is then determined iteratively without a priori
26 assumption. The retrieved two-wavelength extinction at each layer is then converted to particle effective
27 radius assuming a lognormal distribution. The algorithm is tested on synthetic data, Raman lidar
28 measurements and then finally the real CALIOP backscatter measurements. Results show improvements over
29 the CALIPSO operational algorithm by comparing with ground-based Raman lidar profiles.

30 **1 Introduction**

31 Atmospheric aerosols have important impacts on the physical and chemical processes in atmosphere, as well
32 as the climate system and public health. Optical properties of aerosols are critical in quantifying their radiative
33 effects in the Earth's climate system. Moreover, the vertical distribution of aerosol properties, such as its
34 extinction coefficient and particle size, is one of the key elements to assess climate effect (IPCC, 2023).
35 Direct aerosol radiative forcing, which plays an important role in the Earth's energy budget, is impacted by
36 the vertical distribution of aerosols, especially that for absorbing aerosols (Goto et al., 2011; Eswaran et al.,
37 2019; Zhang et al., 2022). The vertical profiles of aerosol optical properties is also essential estimating the
38 solar heating rate (Kudo et al., 2016), and establishment of aerosol parameterization schemes for satellite
39 remote sensing (He et al., 2016). Although its importance is widely recognized, aerosol vertical distribution
40 is very difficult to monitor globally. Lidar is a major technique for obtaining the profiles of the aerosol
41 properties, which has been used in ground-based and satellite remote sensing systems. Especially, spaceborne
42 lidar is an effective way to observe the global distribution of aerosols. The Cloud-Aerosol Lidar with
43 Orthogonal Polarization (CALIOP) on the CALIPSO (The Cloud-Aerosol Lidar and Infrared Pathfinder
44 Satellite Observation) satellite, the only long-term orbiting spaceborne lidar to date, was launched on 28 April
45 2006. The CALIOP is a three-channel Mie-scattering lidar system, which contains two wavelengths of
46 532 *nm* (perpendicular & parallel polarization channel) and 1064 *nm*. It is the first polarization lidar to
47 provide three-channel elastic backscatter signals of global atmospheric measurements. The official aerosol

48 retrieval algorithm of CALIOP involves three modules, namely the Selective Iterated BoundarY Locator
49 (SIBYL), the Scene Classification Algorithm (SCA), and the Hybrid Extinction Retrieval Algorithms
50 (HERA). The HERA algorithm requires a lidar ratio (extinction-to-backscatter ratio of aerosols), which is
51 provided by the SCA. The SCA uses three CALIOP channels (532 *nm* parallel, 532 *nm* perpendicular and
52 1064 *nm* channels) to obtain the lidar ratio from the 6 groups of assumed column-averaged lidar ratios based
53 on a clustering of aerosol optical properties measured at surface stations (Winker et al., 2009).

54 The lidar ratio is dependent on the chemical composition, shape, particle size distribution of aerosols,
55 as well as the lidar wavelength (Burton et al., 2012), which is a critical parameter required for solving the
56 Mie-scattering lidar equation using the Klett (Klett, 1985) or Fernald (Fernald, 1984) methods. Previous
57 studies have developed algorithms to determine the lidar ratio iteratively for two-wavelength Mie scattering
58 lidars. Potter (1987) first introduced the two-wavelength lidar inversion technique to retrieve the aerosol
59 transmission with a constant lidar ratio in two independent wavelengths. Ackermann (Ackermann, 1997,
60 1998) developed an iterative method to obtain the variable lidar ratio from two-component (i.e., molecule
61 and aerosol) atmospheres by transcendental equation. Rajeev and Parameswaran (1998) proposed a new
62 method using the Mie theory calculated aerosol optical properties with Junge distribution of aerosols to
63 determine the lidar ratio by iteration. Lu et al. (2011) made an attempt to improve the two-wavelength lidar
64 inversion by iterative method, but failed to consider the size distribution of aerosols which may introduce
65 uncertainties in the inversion. Moreover, these studies mostly only gave the aerosol extinction profile without
66 retrieving the vertical distribution of aerosol size information. The algorithms were also mostly applied to
67 theoretical data or ground lidar measurements. The application to space lidars such as CALIOP is challenging
68 and thus limited.

69 In view of the above discussions, this study aims to provide a modified two-wavelength lidar
70 inversion algorithm to retrieve the vertical distribution of both aerosol extinction and particle effective radius,
71 avoiding the complex calculation confronted in the previous two-wavelength lidar inversion methods. The
72 algorithm is tested on synthetic data, surface Raman lidar and is finally applied to CALIOP measurements,

73 in order to better demonstrate its operational feasibility. The paper proceeds with descriptions of the inversion
 74 algorithm in Sect. 2. Sect. 3 presents the application of the algorithm to the Raman lidar and CALIOP with
 75 an analysis of retrieval uncertainties provided in Sect. 4. The study concludes in Sect. 5 with a brief discussion
 76 in the context of relevant lidar algorithms.

77 **2 Description of the lidar inversion algorithm**

78 The modified inversion algorithm retrieves the profiles of aerosol extinction and effective radius at two
 79 wavelengths, by solving the lidar equation using the Fernald method (Fernald, 1984) with a look-up table
 80 approach in the iteration procedure.

81 **2.1 Solving the lidar equation**

82 For each wavelength with a complete overlap between the fields of view of the laser and of the receiver, the
 83 lidar equation with calibration and range-correction can be expressed as:

$$84 \quad \beta'(R) = \frac{P(R)R^2}{E_0\xi} = [\beta_m(R) + \beta_p(R)]T_m^2(R)T_p^2(R), \quad (1)$$

85 where

$$86 \quad T^2(R) = e^{-2\tau(R)}, \quad (2)$$

$$87 \quad \tau(R) = \int_{R_0}^R \sigma(r)dr, \quad (3)$$

88 In Eq. (1-3), $\beta'(R)$ is the attenuated backscatter coefficients (calibrated and range-corrected signal)
 89 from distance R ; $P(R)$ is the measured signal after background subtraction and artefact removal from
 90 distance R ; E_0 is the average laser energy for the single-shot; ξ is the lidar system parameter; $\beta(R)$ and $\sigma(R)$
 91 are the volume backscatter and extinction coefficient at range R , respectively; $T^2(R)$ is the two-way
 92 transmittance from the lidar to the scattering volume at range R ; $\tau(R)$ is the optical depth at range R ; and the
 93 subscripts M and P denote the portions of air molecules and aerosols, respectively.

94 In order to facilitate calculation, the transmittance of air molecules $T_m^2(R)$ is separated from $\beta'(R)$
 95 to obtain the $E(R)$ as

$$96 \quad E(R) = \frac{\beta'(R)}{T_m^2(R)}, \quad (4)$$

97 As is well known, lidar back scatter signal is also subject to multiple scattering effects. These effects
 98 are typically small for low to moderate aerosol loading, and is only significant for optically thick clouds
 99 (Winker et al., 2009). Therefore, we neglect multiple scattering effects here and consider that the lidar ratio
 100 ($S(R)$) of aerosols is range dependent in single-scatter approximation, which can be written as

$$101 \quad S(R) = \frac{\sigma_p(R)}{\beta_p(R)}, \quad (5)$$

102 In the following, we use the Fernald method (Ackermann, 1998) to obtain the aerosol extinction
 103 coefficient at distance R as

$$104 \quad \sigma_p(R) = S(R) \left\{ E(R) e^{-2 \int_{R_0}^R S(r) \beta_m(r) dr} \left[C - 2 \int_{R_0}^R E(r) S(r) e^{-2 \int_{R_0}^r S(r') \beta_m(r') dr'} dr \right]^{-1} - \beta_m(R) \right\}, \quad (6)$$

105 where

$$106 \quad C = \frac{\beta'(R_0)}{\beta_p(R_0) + \beta_m(R_0)}, \quad (7)$$

107 The backscatter and extinction coefficient of air molecules can be determined with the Rayleigh
 108 scattering theory with the observed atmospheric profile (Bodhaine et al., 1999) as

$$109 \quad \sigma_m(R, \lambda) = \frac{C_s(\lambda) P(R)}{T(R)}, \quad (8)$$

$$110 \quad \beta_m(R, \lambda) = \frac{\sigma_m(R, \lambda)}{\frac{8\pi}{3} k_{b\omega}(\lambda)}, \quad (9)$$

111 Where $P(R)$ and $T(R)$ are the atmospheric pressure (hPa) and temperature (K) at distance R , respectively.
 112 $C_s(\lambda)$ and $k_{b\omega}(\lambda)$ are the atmospheric molecular constant related to the wavelength λ . Hostetler et al. (2006)
 113 suggested the values of $C_s(\lambda)$ and $k_{b\omega}(\lambda)$ at 532 nm and 1064 nm as $C_s(532 \text{ nm}) = 3.742 \times 10^{-6}$ (K/
 114 hPa/m); $C_s(1064 \text{ nm}) = 2.265 \times 10^{-7}$ (K/hPa/m); $k_{b\omega}(532 \text{ nm}) = 1.0313$; $k_{b\omega}(1604 \text{ nm}) = 1.0302$.

115 Thus, the aerosol extinction coefficient profiles can be obtained by Eq. (6) with an unknown variable
 116 of the lidar ratio. The two-wavelength lidar can give two independent profiles of attenuated backscatter

117 coefficients at different wavelengths, from which the aerosol extinction coefficient profiles can be calculated
 118 by assuming the lidar ratios at the two wavelengths.

119 For two wavelengths (λ_1 & λ_2), the Ångström exponent (AE) at distance R is defined as:

$$120 \quad AE(R) = -\frac{\ln\left[\frac{\sigma_p(R, \lambda_1)}{\sigma_p(R, \lambda_2)}\right]}{\ln\left[\frac{\lambda_1}{\lambda_2}\right]}, \quad (10)$$

121 Because AE is related to particle ~~size distribution~~effective radius, which is a primary factor
 122 determining the lidar ratio, an AE -lidar ratio relationship can be established and used to determine the lidar
 123 ratio at each layer, which can then be used to retrieve aerosol extinction profiles from two-wavelength lidar
 124 measurements.

125 2.2 Look-up table

126 By assuming spherical particles size distribution, the aerosol extinction coefficients and backscatter
 127 coefficients can be calculated by Eq. (11-12):

$$128 \quad \sigma_p(\lambda) = \int_{r_{min}}^{r_{max}} Q_e(\lambda, r) \pi r^2 n(r) dr, \quad (11)$$

$$129 \quad \beta_p(\lambda) = \int_{r_{min}}^{r_{max}} Q_b(\lambda, r) \pi r^2 n(r) dr, \quad (12)$$

130 Where $n(r)$ represents the volume-size distribution of particles; r_{max} and r_{min} are the maximum and
 131 minimum of the particle ~~effective~~radius, respectively; $Q_e(\lambda, r)$ and $Q_b(\lambda, r)$ denote the extinction and
 132 backscatter ~~efficiency~~efficiencies of the particle (the scatter factor of the particle at 180°) with size r at
 133 wavelength λ , respectively. The size parameter is defined as $x \equiv 2\pi r / \lambda$, where $1 < x < 50$ for typical
 134 aerosols and thus the Mie scattering theory (Mishchenko and Yang, 2018) can be applied.

135 As the limited information provided by two-wavelength lidar, we assume the volume-size distribution
 136 of aerosols conform to the lognormal distribution, and the size distribution is expressed as follows (Deshler
 137 et al., 2003; Hara et al., 2021):

$$138 \quad n(r) = \frac{N}{r \ln s_d \sqrt{2\pi}} e^{-\frac{(\ln r - \ln r_0)^2}{2(\ln s_d)^2}}, \quad (13)$$

139 Where N is the total particle concentrations; r_0 and s_d are the median radius and the geometric standard
 140 deviation of aerosol size distribution, respectively. ~~When we assumed a constant s_d for the same aerosol type,~~

141 ~~the AE can be calculated with a given r_0 value. The particle-~~The particle size distribution is represented by
142 its effective radius (\bar{r}) is defined by:

$$143 \quad \bar{r} = \frac{\sum n(r)r^3}{\sum n(r)r^2}, \quad (14)$$

144 For convenient calculation, we assume a constant s_d for the each aerosol type, and the relationship between
145 AE and \bar{r} can be established with given r_0 values.

146 We choose the six types of aerosols with their parameters in Table 1, which is consistent with the
147 aerosol classification used in the operational algorithm of CALIOP (Winker et al., 2009). From Table 1, Type
148 3 denotes the scattering aerosols, Type 2 shows both strong scattering and absorption, whereas other types
149 are moderate scattering or absorbing. Combining Eqs. (5, 10-14), the relationship between Ångström
150 exponent (AE) and lidar ratio (S), as well as that between AE and particle effective radius (\bar{r}) can be
151 formulated as look-up tables for different refractive indices, as shown in Figure 1. Note that in Figure 1, it is
152 easy to determine $S_{532 \text{ nm}}$, $S_{1064 \text{ nm}}$ and \bar{r} by the unique AE calculated from the lidar equation for a fixed
153 aerosol type.

154 **2.3 The iterative inversion procedure**

155 After constructing the look-up table, we design the following iterative procedure to simultaneously retrieve
156 aerosol extinction and effective radius profiles. Firstly, we calculate the extinction coefficients ($\sigma_{532 \text{ nm}}$ &
157 $\sigma_{1064 \text{ nm}}$) of two wavelengths (532 nm & 1064 nm) from an initial guess of the lidar ratios ($S_{532 \text{ nm}}^0$ &
158 $S_{1064 \text{ nm}}^0$) by solving the lidar equation (Eq. 6), then obtain the Ångström exponent (AE) through Eq. (10).
159 Secondly, the look-up table are used to determine a set of new lidar ratios ($S'_{532 \text{ nm}}$ & $S'_{1064 \text{ nm}}$), which is
160 used to calculate the new $\sigma_{532 \text{ nm}}$ & $\sigma_{1064 \text{ nm}}$ and Ångström exponent (AE'). This procedure is repeated until
161 the difference between the updated AE' and previous AE reduces to a very small value (e.g., 10^{-3}). The final
162 AE is converted to effective radius from the AE - \bar{r} look-up table, and the final values of $\sigma_{532 \text{ nm}}$, $\sigma_{1064 \text{ nm}}$,
163 $S_{532 \text{ nm}}$, $S_{1064 \text{ nm}}$ and \bar{r} are the retrieved results of this layer. The above iterative algorithm is summarized
164 into Figure 2.

165 Although in theory, our algorithm can retrieve aerosol extinction and effective radius at each layer,
166 in reality the measurement noise may cause the inversion of certain layers fail to converge. In these cases,
167 we assume that this layer has the same aerosol type and size distribution as its adjacent layer, and then these
168 two layers are combined into a new layer to continue with the inversion.

169 **2.4 Test of the algorithm with synthetic data**

170 For verifying the feasibility of the inversion algorithm, we first conduct some retrieval tests using synthetic
171 data from Mie scattering and radiative transfer simulations. We assume a hypothesized profile of effective
172 radius, backscatter and extinction coefficients of the aerosols, and use the American atmospheric model in
173 1976 (National Geophysical Data, 1992) for molecular scattering, and calculate the attenuated backscatter
174 profiles according to the lidar equation. We then apply our algorithm to retrieve the aerosol property profiles
175 from these simulated lidar signals and compare them with the initial assumptions.

176 We only present the results for the reflective aerosol model, and results for other aerosol types are
177 similar. The simulated attenuated backscatter profiles for the two wavelengths are shown in Figure 3, and
178 the results of our inversion and their comparison with the assumed profiles are shown in Figure 4. It is clearly
179 seen that the results of the inversion are in good agreement with the assumed profiles. The MAPE (Mean
180 Absolute Percentage Error) between retrieved and assumed profiles of extinction coefficient, average particle
181 effective radius and lidar ratio are all below 0.1%, which proves the validity of the algorithm in theory. Note
182 that typically, selection of aerosol type is critical as incorrect assumption of aerosol refractive index will
183 result in divergence of the algorithm and thus yield no valid retrieval. This also helps us to determine the
184 appropriate aerosol type, i.e., the type that yields the best retrieval results.

185 **3 Application to real lidar measurements**

186 Before applying our algorithm to CALIOP measurements, we first use Raman lidar measurements to test its
187 accuracy as Raman lidars can directly retrieve aerosol extinction profiles without assuming a lidar ratio.

188 3.1 Application to Raman lidar measurements

189 A Raman lidar (Model LR231-D300, Raymetrics S.A, Greece) is installed on top of an 8-floor building at
190 the Peking University site (39°59'N, 116°18'E, 53m above sea level). It can provide the extinction and
191 backscatter coefficient at 532 nm by Raman inversion (Ansmann et al., 1990) without the need to assume
192 the lidar ratio. To test our inversion algorithm, we apply it to the elastic backscatter signals at 532 and 1064
193 nm and compare the retrieved extinction profile at 532 nm with that retrieved with the Raman method. Note
194 that the 1064 nm extinction is estimated using the Angstrom relationship of Eq. (10) and we assume that the
195 532 ~ 1064 nm AE equals the 355 ~ 532 nm AE. But an approximation of AE is used in the inversion at
196 1064 nm, that we approximate the 355 ~ 532 nm AE as the 532 ~ 1064 nm AE to calculate extinction profile
197 at 1064 nm by Eq. (10). We apply the modified inversion algorithm to the cases of four different aerosol
198 types. To facilitate the determination of the initial value, we use the method of remodelling downward
199 attenuated backscatter from ground-based lidar (Tao et al., 2008) to reconstruct the Raman lidar
200 measurements at wavelength of 532 nm and 1064 nm, which are showing Figure 5-8(a).

201 We examined four cases in December 2017, as shown in Figures 5-8. The cases on 2 and 21 December
202 2017 both indicate that the extinction coefficient decreases sharply with altitude, and the maximum values
203 occur near the ground (Figure 6b & 7b). The other two cases on December 1 and 23 respectively show the
204 features of an elevated aerosol layer with maximum extinction found above the surface. In all four cases,
205 our retrieval results (red curves) agree well with those retrieved by the Raman method, with MAPE less than
206 30% in the extinction coefficient profiles. The lidar ratio profiles retrieved by our algorithm also agree well
207 with obtained from Raman method in some ranges, except these spikes at the highest or lowest point, may
208 be caused by the uncertainty of boundary. The aerosol particle effective radius slightly increases with altitude
209 and the peak (corresponding to $\sim 0.1 \mu\text{m}$) appear at $\sim 0.7 \text{ km}$ and $\sim 1.7 \text{ km}$ on 1 and 23 December 2017
210 (Figure 5d & 8d), respectively. Similar results were found by Zhang et al. (2009) and Cai et al. (2022) with
211 aircraft measurements over Beijing and the Loess Plateau in China respectively, which are mainly associated
212 with long range aerosol transport. The variability of particle effective radius profiles in Figure 6d is a typical

213 feature for low (and stable) PBL (Planetary Boundary Layer), which results in both particles and water vapor
214 accumulating near PBL top and thus remarkable hygroscopic growth of particle size may occur (Yang et al.,
215 2020). The case for Dec 21 (Figure 7d) shows relatively large particle size below~1.4km but sharply
216 decreases. This is likely related to the domination of local pollutions and insignificant PBL temperature
217 inversion (Li et al., 2022; Liu et al., 2009; Zhang et al., 2009).

218 **3.2 Application to CALIOP measurements**

219 We further apply our algorithm to real CALIOP measurements. To test its performance, we collocate
220 CALIOP profiles with those from surface-based Raman lidar measurement within the European Aerosol
221 Research Lidar NETwork (EARLINET, www.earlinet.org, (Matthias et al., 2004). Aerosol profiles from the
222 Napoli (southern Italy, 40.838 °N , 14.183 °E , 118 m above sea level), Evora (south-central
223 Portugal, 38.5678 °N, -7.9115 °E, 293 m above sea level) and Warsaw (east-central, 52.21 °N, 20.98 °E,
224 112m above sea level) stations have the best match with CALIOP and high data quality in cloudless sky, are
225 primarily used to validate the retrieval results. The CALIPSO overpass times for the chosen cases and the
226 corresponding horizontal distances between the sub-satellite point and ground-based Raman lidar site are
227 listed in Table 2.

228 To compare with the lidar returns measured by CALIOP (down-looking) and ground-based Raman
229 lidar (up-looking), we still use the method of remodelling downward attenuated backscatter from ground-
230 based lidar (Tao et al., 2008) to reconstruct the downward attenuated backscatter signals for the ground-based
231 Raman lidar. The attenuated backscatter signals of CALIOP was averaged for 163 nearby sub-satellite point
232 profiles (CALIPSO ground track range of about 30 km within 8 s) (Lu et al., 2011; Wang et al., 2007),
233 obtained from CALIOP level 1B products, to improve the signal-to-noise ratio.

234 The attenuated backscatter profiles at 532 nm from CALIOP agree well with those from the Napoli
235 Raman Lidar (NRL), as shown in Figures 9-14(a). The initial altitude of inversion (the upper boundary of the
236 aerosol layer) is determined by the variation of attenuated backscatter signal and volume linear depolarization

237 ratio at 532 *nm*. Comparison between our inversion results, CALIOP operational results and Raman results
238 is shown in Figure 9-14(c).

239 The CALIOP operational product only provides retrievals for three cases considered, namely 20
240 August 2006, 20 June 2007 and 22 July 2007. In all three cases, the aerosol extinction profiles of our
241 algorithm (red curve) appear in better consistency with Raman lidar results, and our algorithm ~~cut~~ reduces
242 the mean MAPE between the retrieval of extinction profiles in CALIOP and Raman lidar from 74% (CALIOP
243 operational product) to 37%. Our algorithm successfully corrects the overestimation for the August 20, 2006
244 and July 22, 2007 cases. For the June 20, 2007 case, the operational results show a lower peak at ~1.7 km
245 and a secondary peak at ~4 km, both of which are absent in the Raman profile, and our results agree well
246 with Raman in both the shape and magnitude. In the other three cases, CALIOP does not provide Level 2
247 retrieval results. Our algorithm is able to retrieve and the extinction profiles agree well with Raman lidar
248 observations. Our retrievals do show more fluctuations compared to Raman lidar, possibly due to the noises
249 in the attenuated backscatter profiles of CALIOP. Because Raman lidar does not provide retrieval of aerosol
250 effective radius profiles, we compare the lidar ratio profiles by our algorithm and the Raman algorithm.
251 Overall, our algorithm produces lidar ratios varying in a relatively small range around 50, whereas Raman
252 lidar ratios can vary from ~10 to 200. Also, the Raman lidar ratios tend to change sharply at the highest or
253 lowest point, which may be caused by the inversion errors at the boundary. By removing these spikes, the
254 differences of the lidar ratio between CALIOP and Raman is obviously reduced. In general, the aerosol
255 particle effective radius increases with altitude, similar to Figures 5d and 8d, but the fluctuations of the
256 profiles may also be caused the noise in the CALIOP measurement.

257 When examining the CALIOP backscatter measurements, we found that the backscatter signal at 1064
258 nm is often stronger than that at 532 nm after 2010, which is unphysical and possibly due to issues such as
259 calibration and lidar degradation. As a result, the remodeled backscatter profiles of CALIOP appear noisier
260 and do not exactly match those from Raman lidar for the Evora and Warsaw stations, which only have
261 collocated measurements in 2019 and 2020 (Figure 15-19a). Our retrieved extinction profiles also agree

262 reasonably well with those by Raman lidar (Figure 15-19b), with the lidar ratio profiles and aerosol particle
263 effective radius profiles similar to the cases at Naples. By contrast, the extinction profiles of the official
264 CALIPSO product show large deviations from the Raman profile with unphysical spikes (Figure 16b),
265 incomplete profiles (Figure 17&18b) or no retrievals (Figure 15b).

266 **4 Uncertainty analysis**

267 Uncertainties in aerosol extinction and effective radius profiles retrieved by our two-wavelength inversion
268 algorithm are mainly due to measurement noise (e.g., the signal statistical error, the estimations of molecular
269 optical properties, etc.), calibration errors, and assumption errors. In this section, we further examine the
270 errors associated with the assumptions in the algorithm.

271 First, the single-scattering approximation is used in solving lidar equation, as multiple scattering effects
272 in aerosol layers are generally small and are currently neglected for CALIOP (Winker et al., 2009). We limit
273 the application of our algorithm to clear sky weather conditions to reduce this error, but this error is very
274 difficult to quantify.

275 Second, the errors in the aerosol refractive index, size distribution and sphericity assumptions in look-up
276 tables can also introduce errors in solving the lidar equation. The lognormal distribution assumption of
277 aerosol volume-size distribution may make the algorithm fail to converge in other actual size distributions.
278 For example, using data generated by Junge distribution (a simpler aerosol size distribution), the algorithm
279 cannot yield valid retrieval results. Similar outcome is noted for non-spherical particles or aerosol types
280 significantly different from the assumed type.

281 Finally, we consider assumption and retrieval uncertainties as a perturbation in the lidar ratio and attempt
282 to quantify its effect on the retrieved profiles. We increase the lidar ratio profiles at 532 nm and 1064 nm
283 from the look-up tables by $\pm 10\%$ before calculating the synthetic attenuated backscatter profiles, which
284 makes the synthetic data do not entirely match the look-up table. The retrieval profiles exhibit mean MAPE

285 less than 14% (in 10% case) and 17% (in -10% case), indicating that the algorithm is comparatively robust
286 to noise.

287 **5 Summary and discussion**

288 In this study, we described a modified lidar inversion algorithm to retrieve aerosol extinction and size
289 distribution simultaneously from two wavelengths elastic lidar measurements. Its major advantage over the
290 operational CALIOP algorithm is that the lidar ratio of each layer is determined iteratively by the lidar ratio-
291 AE look-up table. The algorithm was applied to the ground-based Raman lidar measurements at the PKU
292 site, as well as to CALIOP measurements. The comparison results indicate that the retrieved aerosol
293 extinction coefficient profiles by our method using CALIOP attenuated backscatter measurements are in
294 good agreement with Raman lidar measurements. Characteristics of aerosol effective radius profiles are also
295 retrieved, which can be used as a reference for aerosols size information.

296 In comparison with the iterative method by transcendental equation (Ackermann, 1997, 1998), our
297 inversion uses the look-up table to simplify the complex calculation. Cao et al. (2019) develop a lidar-ratio
298 iteration method to invert the particle-size distribution with assumed Junge distribution, but the method was
299 just used in simple simulation without actual tests. Although Lu et al. (2011) invert the aerosol backscatter
300 coefficient profiles from CALIPSO lidar measurements by iterative method, failed to consider the size
301 distribution of aerosols which may introduce uncertainties in the inversion. Compared with other modified
302 CALIOP inversions by combining other measurements, such as ground-based lidar (Wang et al., 2007), our
303 inversion is weaker by the space-time limitations.

304 However, this study still bears certain limitations. The current algorithm is primarily suitable for fine
305 mode spherical particles, such as urban pollution, and considers the change of aerosol size (thus lidar ratio)
306 with altitude, due to long range transport, vertical mixing, hygroscopic growth, etc. Non-spherical particles
307 such as dust will be explored in the next step, possibly by taking advantage of the depolarization ratio
308 (Gialitaki et al., 2020; Kahnert et al., 2020; Luo et al., 2022; Luo et al., 2019) measurement that is not used

309 here. Another drawback is that although the algorithm does not need to assume a lidar ratio, the complex
310 refractive index still needs to be assumed. As discussed above, the lidar ratio is very sensitive to the imaginary
311 part and an incorrect assumption may induce errors or even makes the algorithm unable to converge.
312 Therefore, this algorithm is mostly suitable when there is no significant change in aerosol type vertically.
313 Finally, the polarization channel of CALIOP may contain additional aerosol type information but is only
314 used when determining the initial refractive index (excluding dust) here. We also plan to refine our look-up
315 table by incorporating polarization in order to improve the accuracy of the retrieval.

316 **Data availability**

317 All raw data can be provided by the corresponding authors upon request.

318 **Author contributions**

319 LC and JL planned the research; LC, JL, JR, CX, and LZ developed the algorithm; LC and JL analyzed the
320 results; LC and JL wrote the manuscript.
